PLANTING.—A good many people suppose that a potato grows upon the root of the plant, but this is not the case. A potato is the swollen end of an underground branch, and the eyes of a potato are simply the buds of this branch. As the sprout or branch from a potato eye comes up through the ground, it makes nodes, joints or buds, and from these underground buds new branches start, of which the swollen end is the potato. In some varieties these underground buds are much farther apart than in others; hence we must needs study our variety to know how deep to plant to get a good yield. As a rule, those varieties that grow compactly in the hill are the ones that grow these buds closest together, and may be planted shallowest; while those that grow the tubers scattering in the hill are opposite. However, the best average depth to plant is four to five inches. Varieties that grow small vines may be drilled much closer together in the rows than those with rank vines. If to be planted by hand, drop pieces of one to two eyes from 10 to 18 inches apart. The seed or blossom end of each potato should be cut off and thrown away. However the planting may be done, either by machine or hand, a good ridge should be thrown up over each row, as it will be of much use when we come to the cultivation. Before the potatoes are up and weeds start, harrow twice by lapping the harrow half way, and as you have a ridge to guide you keep the horses off the rows. As soon as you can see the potatoes in the rows harrow as before and keep the horses off the rows. I desire especially to emphasize *keeping the horses off the rows.* Continue cultivation with any tool that will cultivate very shallow until vines prevent or the crop is ripe. Cultivate often, level, shallow and especially as soon as the ground is in fit condition after each rain. Frequent culture will be an advantage with respect to

INSECTS AND DISEASE.—Any injury to the vines is a check to the growth, and I would advise for killing the bugs: 11 ounces acetate of lead and four ounces arsenate of soda dissolved, each in two or three gallons of water, to which is added enough water to make 150 gallons in all; then add one gallon of cheap molasses and spray the vines. The only thing we know to do for blight, is to spray with Bordeaux Mixture; and the only thing we *need* to do for scab, is to immerse the potatoes before they are cut for 1½ hour in the following: In two gallons of boiling hot water dissolve two ounces of corrosive sublimate, to which add 13 gallons of cold water, and it is ready for use. I very much prefer to have the tubers dry before cutting.

THE EFFECT OF SOUTH DAKOTA CLIMATE ON A POTATO. FIG. 115.

VARIETIES.—I give herewith a list of varieties we have been using for our crop alone, and list none that have not been given a thorough trial: Extra early, Acme and Burr's No. 1; second early, Early Norther and Express; first late, Livingston's Banner and Livingston; late, Rural New-Yorker No. 2 and Pink Gem.

Tolono, Ill.

Getting Ready to Plant Potatoes.

Last Spring many farmers waited until time to plant before making any preparations for treating the seed for scab. Then when the ground was fitted and marked out, it was found that no formalin nor corrosive sublimate was on hand, and it was then decided to forego the seed treatment for "this time." This decision saved a little time and extra trouble, but did it pay, in a majority of cases? Most certainly it did not. In several instances farmers have stated to us, during the past Winter, that it was the last time they would fail to treat their seed potatoes before planting. Some of them declared they lost enough in the yield and sale of marketable tubers to pay for treating the seed many times over. We have repeatedly tried all plans, and found the best one to have the formalin procured early and treat the seed just before planting. We prefer formalin to corrosive sublimate, every time. It bothered us to procure the formalin last year in Battle Creek, as the druggists kept it only in limited quantities. For the last two years we have had to order from Chicago or Detroit firms. We have notified our druggist early this season, and he will have a supply on hand when wanted. Several other farmers in this section have asked us to order for them, so that we believe formalin will be thoroughly tried by potato growers hereabouts.

Last Spring we used two oil casks to soak the potatoes in. Each cask was filled a little less than two-thirds full of water. We used about one-half pint of commercial formalin to each 15 gallons of water. As the casks were large, we used binder twine sacks to hold the potatoes in the solution, putting three bushels in each sack. The seed was soaked for two hours, exactly, and one man attended to this job, occasionally churning the sacks up and down in the casks, so as thoroughly to soak the whole surface of each tuber. When ready to commence soaking, we had a big load of potatoes in bushel crates on the low-down truck. These we unloaded near the barrels, and the soaked seed was spread over the truck platform to dry. As soon as a load of treated seed was ready it was taken to the center of the potato field. Commencing on the rear end of the truck, two men cut the seed as fast as needed for use in the two-horse planter. Considerable seed had been cut the day previous, so that the planter was kept constantly busy all day. So far we have cut all our seed by hand, and have never had any experience with the machine cutters. We endeavor to cut pieces to two eyes, but is is difficult to pay close attention to this rule when in a hurry.

Some of our seed two years ago was quite scabby. Fig. 117 shows how bad some potatoes were. They were all Carman No. 3, and Fig. 118 shows some fine specimens. Some of the scabbiest potatoes were treated with formalin and planted in a row by themselves. When dug, the potatoes in this row were just as large and smooth as the others. We prefer to use formalin because it is not so dangerous to handle as corrosive sublimate, and can be put into almost any kind of a receptacle. We do not find germination materially retarded by soaking seed in the formalin solution. Last year we cut some seed potatoes directly they were taken from the solution, without any injury to the hands or clothes. Formalin cost us about 50 cents a pound two years ago, and 40 cents last year. We used nearly two pounds to treat about 45 bushels of seed. This is a little stronger than may have been necessary, but it did no harm, and accomplished an immense amount of good to the resultant crop, and to our own feelings as well. For planting a large acreage, we should arrange to handle the seed

more conveniently when soaking in the formalin solution, so as to avoid lifting heavy sacks full of potatoes in and out of the barrels. However, we had very little trouble in this respect. We expect to plant the Carman No. 3 again this year for our main crop.

Michigan. J. H. BROWN.

SPRAYING FOR THE SAN JOSE SCALE.

Crude petroleum was applied to peach trees for the San José scale in the latter part of March. Fruit buds are backward and in good condition. The oil is put on mostly by kerowater pumps, but occasionally it is sprayed with a plain pump or brushed on with a brush. Last season's treatment of the scale was not very satisfactory. In no case has it been entirely killed, and in many cases not even checked by the use of petroleum. This is not because the oil will not kill, but because of the virulence of the pest and the extreme difficulty of touching all the scale on the tree with fatal effect. Another explanation of the discouraging results of last Spring's work is the unusually favorable season we had last Fall for the late development of the scale. One large peach orchard belonging to the president of the Tidewater Oil Co., was sprayed with everything favorable to a successful job. Now many of the trees are dead with scale, and the orchard is being sprayed again. A striking test of what difficulties are in the way of eradicating the San José scale is seen in the case of a small peach orchard near here, two years old last Spring. The owner, a careful man, painted the trees with undiluted petroleum from the ground to the tips of the branches, taking plenty of time, and doing a thorough job. I walked through that orchard the other day, and found every tree healthy, but there were few on which scale could not be detected. There seemed to be more near or under the buds than anywhere else, but there were enough if they are going to spread as they did last season, soon to overrun the orchard.

In four different orchards that came under my notice, trees, in greater or less numbers, were killed by the oil, which was due, no doubt, as Prof. Smith has explained in THE R. N.-Y., to an impure grade of oil. I have not learned of any trees being killed by oil that was sprayed on. The fruit grower who spoke of the San José scale as a "bugaboo" is living in a fool's paradise. Constant watchfulness and much labor will be required to save our fruit trees from destruction.

Whitehouse, N. J. G. D.

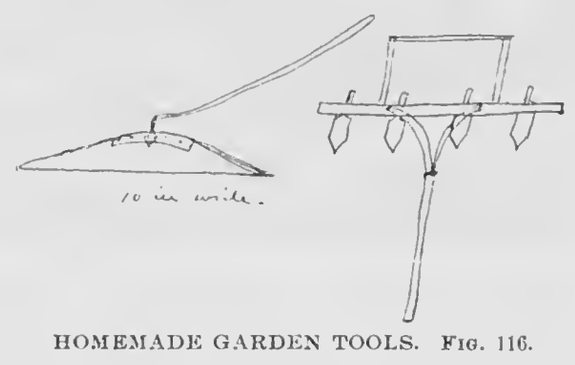
A NORTHERN FARMER'S GARDEN.

How Planted and Cared For.

BEST OF THE FARM.—I consider the garden the best paying part of the farm. I keep the soil rich; every year I put on as much barnyard manure as I can plow in. I plow it with a sidehill or reversible plow, turning the furrows all one way. I plow it deep and fine, not cutting a furrow over four or five inches wide. This makes the ground light. I do not drag it, as the horses walking on it, would make it hard. I rake it off well with a garden rake, picking out roots, sods and stones if I find any. I begin in the middle and rake each way, and when it is raked there is not a track upon it. Then I put a line across one side, mark it straight, take a homemade "marker" that marks and makes the drills at the same time. I make this marker and driller out of a piece of 3x3 timber, about 4½ feet long, I bore four one-inch holes, 15 inches apart, for the markers, two other holes for the handles and two holes for the tongue that I draw it by. The markers are one inch thick, four inches wide and about 12 inches long, and cut down to a point to make the drills. The handles are two feet long with a cross piece from one to the other. The tongue is about six feet long, of green timber. I slip an iron ring down about 18 inches on one end, split that end and spread it to make the tongue bracing. It is shown at Fig. 116. Then I get some one to draw or hold it for me, run outside leg or driller in straight mark I have made and then turn back across the garden, making three drills each time, and running one leg in last drill made. This keeps them all even and saves a lot of work.

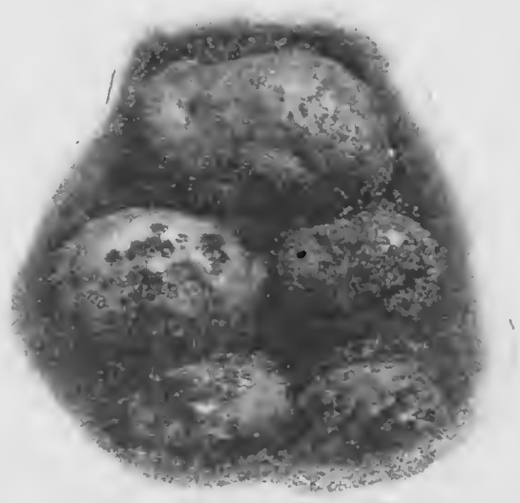
SOWING THE SEED.—In these drills I sow my seeds. Usually in the first drill I sow radishes, next drill lettuce, two drills; salsify, two drills; parsnips, onions, beets, carrots, mangels, beans, tomatoes, cabbage, all in these straight drills 15 inches apart. Then I cover carefully with a hoe, patting the drills smooth and pressing the earth down on the seeds, and when it is all done it looks very well. Sometimes I sow fertilizer in the drills; sometimes I use hardwood ashes. It makes the plants grow and worms and bugs do not like it. In another part of the garden I plant melons, cucumbers, sweet corn, more beans, Summer squash, etc. I sow the garden peas in straight drills, drive stakes, stretch a wire over each drill and hang the brush on the wire. Now as I have all this weeding to do, with no help from the women, I am careful not to let the weeds get much start of me. I have a hoe that I had the blacksmith make. It is made of the point of a cradle scythe with shank riveted on to drive into hoe handle. It is thin, and I keep it sharp by grinding. It cuts about 10 inches wide, and is made like Fig. 116. It is light, the points are sharp and you can hoe up to a plant and not touch it. This worked so well that I had another made of the wide part of the blade for general hoeing. I can do more work and do it easier than I can with a common hoe.

THE CROP.—We dig none of our salsify or parsnips until Spring. They are fine. As soon as snow is off



HOMEMADE GARDEN TOOLS. FIG. 116.

the chives start up, and cut up in vinegar they are a very good substitute for onions. We start tomatoes in boxes, but for two years now I have sown one drill when I made my garden; did not transplant, or fuss with them much, but got our best crop from them—later, of course, but more of them, better and firmer. I plant four varieties of sweet corn, and we have it until frost comes. With this marker I can put in a large garden in a few hours. I can hoe it quickly, if taken in time, and not much weeding to do. But when I am so busy at other work that I cannot



POTATOES FROM UNTREATED SEED. FIG. 117.

attend to it at just the right time I am sorry for myself. On one such occasion I made a weeding stool that was a source of comfort to a weary spinal column. I set my cabbage plants about 2x2½ feet apart; put hen manure mixed with barnyard manure in the hills and get good cabbage. If the cutworms trouble them, I take a teaspoon and put a row of fertilizer around each plant as close as I can and not touch the plant. Cutworms do not enjoy it and do not seem to crawl over it. It makes the cabbage grow. If the green worms appear on the leaves we sprinkle, while dew is on, with fine black pepper; use no poison on cabbage. In this garden we raise more vegetables than we can use; give some to the neighbors and sell some and find it profitable as well as pleasurable. Last year the worms or maggots commenced on my Black-

POTATOES FROM TREATED SEED. FIG. 118.

seed onions. I put unleached ashes upon them, scattered it right on to the tops, and it stopped their work. I sow Black-seed thick, and then thin out later when we want the little onions to eat. I leave them pretty thick. I have seen nice onions grow where there were five onions in a bunch, four of them upon the ground and the fifth on top, only touching the ground where the roots went down between the others. I have set my cabbage on same ground for 10 to 12 years, and no club-foot has appeared. I often have to pull them a little to keep them from bursting open. S. C. A.

Riparius, N. Y.

THE GREAT NEED OF VEGETABLE MATTER

Great Success with Cowhorn Turnips.

A great deal of discussion is constantly going on in the agricultural papers about the improvement of the soil by means of green manuring. Most of the writers on the subject advise the use of legumes, to the exclusion of other plants. At the farmers' institute held here last February, Mr. Seeds, a farmer from Juniata County, presented another feature of the subject, viz., the raising of the potash from the subsoil and placing it where surface-growing plants could make use of it. Mr. Seeds was crowded into his method by the lack of means and the inability to get a satisfactory stand of legumes. On a hard clay loam, where four inches was the depth that could be plowed, he commenced operations. He first used the Purple-top Strap-leaved turnip, but discarded it because it grew on top of the ground. Something with a long root that would mature in the Fall, so that the ground could be used in the Spring was desired. A search of the catalogues revealed the Cowhorn turnip, which bid fair to meet the requirements. Seed was purchased and sown in the corn at time of the last cultivation. This proved successful. Individual specimens measured over three feet, with one-half or more beneath the surface. Here was a plant breaking up the subsoil, raising the potash, and adding humus to the soil at the estimated rate of $50 worth of fertility per acre at a cost last year of only 54 cents per acre. There is no hauling manure or bothering with fertilizers. There is no lime or wood ashes to blind one when spreading them, but $50 worth of fertility right where you want it, to say nothing of the benefits gained by loosening up the soil. In five years this farm has been raised from a deserted spot to a profitable home.

With the turnip seed is now sown Crimson clover, and Mr. Seeds assured his audience that the one field of oats that more than paid expenses last year in the Juniata Valley was the one on his own farm, of which he exhibited a photograph. He attributes his success to "vegetable matter in the soil." Other photographs of a field of Red clover as high as his waist, a field of corn, and his field of Cowhorn turnips certainly were encouraging to men on run-down farms. If a man can't grow Crimson clover let him grow what he can—corn it may be—and keep at it until he can get what he wants. I send you these few remarks to help others who are perplexed about these problems. Look at the woods, they are fertile, and most of the farms we have were woods once. What has become of their fertility? Nature hauls no manure or lime, yet keeps her whole farm in excellent shape. Man alone cries that the land is worn out. Put more vegetable matter in the soil and you double up from both ends—less work and more returns. It seems to me this method is worthy of the widest application.

Shawnee, Pa. CHARLES JOHNSON.

R. N.-Y.—We have heard of cows that tossed a mortgage on their horns, but this story of salvation by the Cowhorn turnips beats the record. We know how this turnip grows.

Facts About Clover Seeding.

I do not know of any case of sowing clover seed as early as December or January in this latitude. I am fully persuaded that most clover seed is sown too late. Ours was put on the ground about middle of March and five or six inches of snow have fallen since. No heavy rains, as yet, have compacted the surface soil; therefore I think the ideal conditions are present with us this year for securing good germination. If ground designed for seeding with clover is thoroughly prepared and is moist in the last of July or August, the best seeding can usually be secured by sowing then. Harrow the seed in lightly and roll. The plants will usually get large enough before Winter to keep them from being injured. I think a part of the trouble we have experienced in recent years in securing a good catch of clover seed is due to lack of humus in the soil. I find that wherever the soil has been kept filled with humus by means of manures or cover crops, or both, we get good seeding, and in near-by fields that are dry and compacted because of this lack of humus the seed either failed to germinate or died later because of the bad physical conditions of the land.

Cornell University. I. P. ROBERTS.

PAT'S CHOICE POTATO.—W. H. Heald, of Sanborn Co., S. D., sends us the odd specimen which is pictured on first page, Fig. 115. It weighed 22 ounces as we received it. Mr. Heald says that the potato was kept in his living room from October until April, so that it was badly wilted. He says it is a late variety, of fine quality. We shall plant it this year. We have formerly received some tremendous tubers from Dakota. The tendency there seems to produce great things, but we have not before seen a tuber that tried to sprawl all over as this one has.

THE COST OF SPRAYING TREES.

Better Hire by the Hour.

Have you any knowledge of the probable cost of spraying apple trees, say of medium size? We are thinking of buying a spraying outfit for general work, and several persons wish us to do work for them, and ask what we are going to charge. As the matter is new to us we shall have to depend on the experience of some who have done spraying. H. B. B.

Rockville, Ind.

I think two cents per tree for 100 or more is the price, not including chemicals, but from what I heard last year, I would prefer to furnish pump and hire help. The tramp sprayers do not do thorough work unless watched, as they want to cover as many jobs as they can. J. GAILEY.

Cayuga Co., N. Y.

As trees vary so much in size and the facilities to get water conveniently are so different I think spraying could be done more fairly to both parties by the day or hour. I should judge that as spraying rigs are now so cheap (that is, a small pump on a barrel) each would prefer to own his rig. Again, the time is so limited for the most important spraying (that is between falling of blossoms and closing of calyx end) that one machine could not cover many orchards.

Wayne Co., N. Y. B. J. CASE.

Accurate Figures From Pennsylvania.

I have never done any spraying for others, and there is no one in this neighborhood who makes a business of it, so I can hardly say what would be considered a fair price for such work; but I have kept a very careful record of time and expense on my own trees, so can tell exactly what it cost me. I will take my oldest apple orchard for an example. This orchard contains 440 trees 25 years old; they are large and thrifty. It required two days for three men, a two-horse wagon and barrel pump throwing two streams to go over it once. Allowing $1 per day for each man and 75 cents for each horse the cost of applying the liquid was $9. It required 22 barrels of liquid, or one barrel for 20 trees; one barrel of sulphate of copper solution cost 20 cents; one barrel of Paris-green and lime (one-fourth pound Paris-green, three pounds lime) eight cents; one barrel Bordeaux Mixture cost 36 cents; one barrel ammoniacal solution carbonate of copper, 24 cents; so that it cost me to spray this orchard of 440 trees with sulphate of copper solution, $13.40; with Paris-green and lime, $10.76; with Bordeaux Mixture, $16.92; with ammoniacal solution, $14.28. This is the actual cost of spraying an orchard of large trees on level ground, with water and everything convenient, and the mixture properly made and carefully strained—so that there was no delay from clogged nozzles, etc. The cost per tree would vary, according to the size of the orchard, the size of the tree, the character of the ground, the ease with which water could be procured and the time required to get to and from the orchard, so that it would be very difficult to fix a definite price per tree. It seems to me the only fair way would be to charge for the material by the barrel, and for the labor required to apply it by the day or hour. GABRIEL HIESTER.

Pennsylvania.

Exact Item of Expense.

We consider the value of the labor of spraying 25-year-old apple trees three times to be 10 cents per tree. If the sprayer furnish the material, using the Bordeaux formula with three-fourths of a pound of Paris-green added to the mixture, the charge will be seven cents extra, making the total cost for three sprayings of each tree 17 cents. When spraying has been done at so much per tree, it has proved a very unsatisfactory method in this locality. The proper way to hire spraying done is to pay a fixed price for a day's labor; two men, $1.50 each, $3; one team, $1.50; one day's labor, $4.50. This includes the use of the spraying machine, but not the cost of the mixture. The mixture we prefer is made as follows: Four pounds blue vitriol; four pounds fresh lime; one pound Paris-green to 50 gallons of water. The more lime the better if it does not clog the machine. Keep well mixed. Spray thoroughly, so that the trees will drip with the mixture. This should be done when five-sixths of the blossoms are off. The differences in the opinions regarding spraying are due to the slipshod methods used by some. Last Spring I sprayed a block of 200 apple trees, using 20 pounds of Paris-green, 60 pounds of blue vitriol and 100 pounds of lime. I sprayed these trees but once, and not a wormy apple was to be found at picking time. The cost of spraying this orchard was $30. I sold from it 900 barrels. The trees were 25 years old. A neighbor having an orchard of 150 trees (also 25 years old) which had been bought at the same nursery and set out at the same time, sprayed once, but instead of using the Bordeaux formula he used a solution of one-fourth pound Paris-green to 50 gallons of water. The work having been poorly done, the result was that he had only 130 barrels of second-grade apples to sell. Another neighbor hired a man to spray his orchard of 300 trees, paying him $10 for labor and material. The man doing the spraying drove through the rows as fast as his horses could walk. The result was unsatisfactory and unprofitable. That man says it does not pay to spray. Spray the trees as you would a small bush. Cover them completely with the fluid. One spraying well done is better than three half done. The spraying not only kills the egg, but keeps the fly from the orchard. I have seen the flies on unsprayed trees at twilight, busy doing their work, while at the same time, on trees sprayed, not one was to be found. M. R. F.

Rushville, N. Y.

Cost of Spraying in Illinois.

The cost of spraying apple trees depends entirely upon the skill of the workman, the efficiency of the apparatus, and the cost of material, including, also, proximity to water supply. We find that some people never learn how to spray economically. Others get at it easily, and soon develop a skill which enables them to do the work cheaply. Our best orchardists in this State are spraying their trees at a cost of about 7 1-5 cents per tree for 10-year-old trees, three sprayings, using Bordeaux-Paris-green solution. I find, however, many people in this State who do not succeed in making the three applications for less than 11½ cents, some even getting as high as 20 cents per tree. This is, of course, the actual cost, and if one were doing it as a business he should have something additional for his trouble. That additional cost would be governed entirely by circumstances, and would vary in different localities. I know of no persons in this State, who are doing the spraying for the entire neighborhood. We, at the University, do not believe in this plan, as it means that some people would have their spraying done at the right time, while others would have to wait for their turn. We are, therefore, doing everything in our power to encourage each grower of fruit to have his own outfit and do his own spraying. We also believe that he is a better man if he has learned to spray. J. C. BLAIR.

Illinois Experiment Station.

A Charge by the Hour.

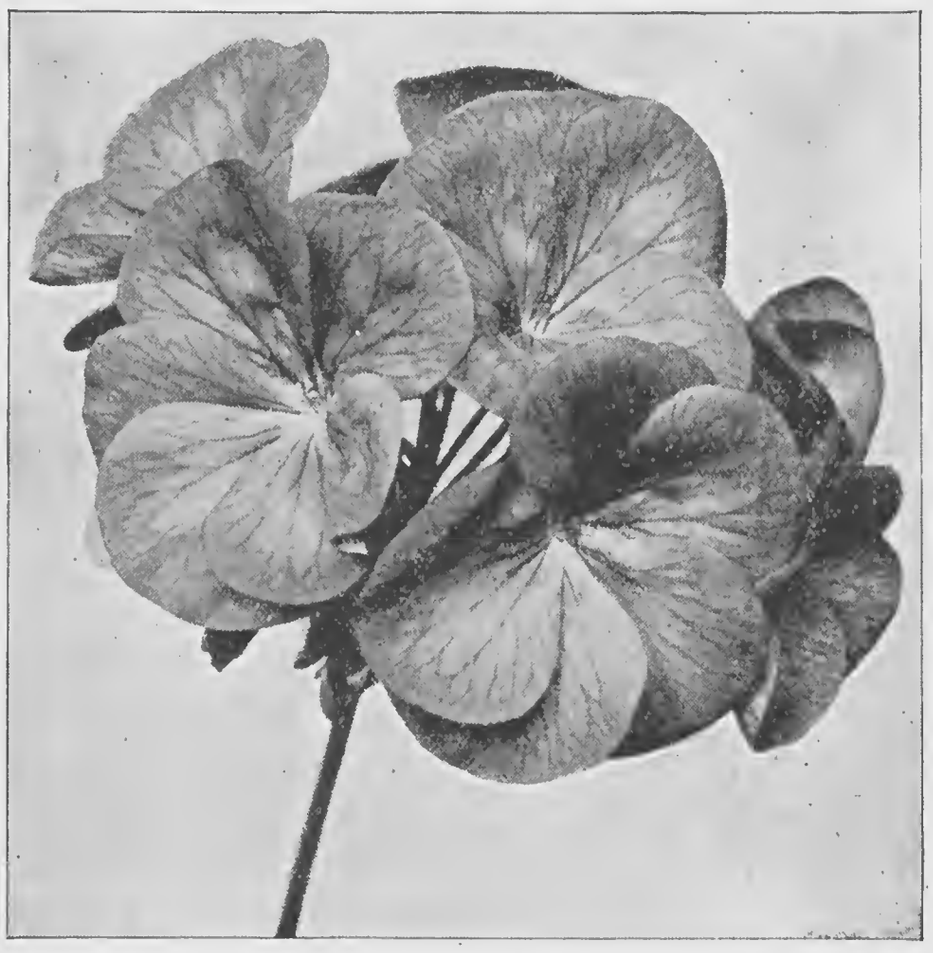
A little experience ought soon to teach a man what he can do it for, and upon what basis to make the charge. If done by the tree everything depends on conditions; whether trees are in full leaf, half leaf, or buds just swelling; large or small; how often he would have to fill up, and how handy the water, etc. Our own experience would lead us to say that it should be done by the day or hour somewhat on this basis: For team, outfit and man (who superintends mixing and directs nozzle), 40 cents per hour. Owner of trees to furnish ingredients and man to pump, or he could furnish team and wagon and proper deductions made for these. If the man who owns the pump furnishes the ingredients, he can charge for what they cost him, including mixing. A self-measuring graduated barrel will be found useful in this case. Spraying has been done in this vicinity at the rate of $1.50 per day for pump and man who directs nozzle. But this seems too low. Brawn will run the pump, but it takes brains to do the mixing and direct the nozzle. The man who does the latter is, in one sense, a professional in his line, and he has a right to charge for his services accordingly; 20 cents per hour for man alone is none too much. At this price he has no sinecure, as those who have followed the wearisome, monotonous job hour after hour can well attest.

Seneca Co., N. Y. W. A. BASSETT.

Own Your Own Pump.

There has been some little spraying done for neighbors who have no sprayer of their own, but so far as I know it has not been very satisfactory. I think in a few cases orchards have been sprayed as low as five cents per tree, and money made for the sprayer at that, but the work was poorly done. I hardly know what would be a fair price for thorough work. I think the most satisfactory way is to own a pump of some size, or at least a half interest in one. I tried owning one with a neighbor for a couple of years, but did not like it. I find it important to be ready at the proper time, and then do thorough work. Unless you have a pump of your own you must wait your turn, and if the weather is not right you are likely to get left. There are times when there will only be one or two days in a week suitable for spraying, owing to wind or rain. I would advise anyone having one acre of orchard to own a good barrel pump and then be ready to spray at the proper time, or as near as possible. F. E. VAN EPS.

Ontario Co., N. Y.



GERANIUM HALL CAINE, CONSERVATORY TYPE. FIG. 119.

SEE RURALISMS, PAGE 292.

AN EXPERIENCE WITH THE PEA LOUSE.

Two years ago we grew peas only for our own use and a few for the neighbors, and the louse just cleaned us out of main crop—Heroine—before we knew it, not giving us a pea. Last year we grew for market in a modest way an acre or less. We were on the watch for the louse, and found it first in the oats and peas, and plenty of them. When oats were cut there wasn't a peavine there. Alongside that field were our market peas, Nott's Excelsior, Advancer and Heroine. Excelsior was practically safe when the louse first appeared. The insects were first seen, of course, next the oat field, a 16-foot grass strip (old hedge) between. I got a "concentrated" whale-oil soap, costing 25 cents per pound, and made a solution of three-fourths pound to five gallons of water, and tried it on the ends of two rows next to oats. It destroyed the louse, but proved too strong for the vines, spotting them somewhat, though not seeming seriously to injure growth. I used a good sprayer and fine spray, spreading the solution freely and saturating the vines. Two days later I added 25 per cent more water and went over the whole piece. Lice were more or less all over it, and ready for business. This application did not seem to injure the vines—spotting them but slightly—but did worry the louse. A few days late I repeated the dose, this time "bushing" the vines with a cedar bush first, and following the bush with the sprayer immediately. Fully 50 per cent of the lice were thrown to to the ground, and as the thing was done in hot part of the day, between the hot ground and oil they staid where they lit. Experiment seemed to show that the hot, hard ground would finish them anyway, but we want in so dry a time to keep the ground soft and consequently it will be a little cooler, so that my dependence was really upon the whale oil. We had peas after all others were through, and our vines were green and reasonably thrifty, notwithstanding the continuous absence of any rain. Those peas were remarked by passing people. The thriftiness (in a dry time) I in part charge up to the use of Clark's Torrent plow in preparing the ground, as well as to holding the louse in check. But my pea ground for this season is that oat lot. I shall plant out that lot and have a supply of whale-oil soap ready, and a cedar bush or two. The raising of peas and oats came up in our Grange recently and I strongly discouraged growing them together, as it makes an ideal breeding place for the louse. One or two made a trial last season, but thought they did not use seed enough. I suspect the louse had something to do with the supposed lack of seed. I make two plantings of Heroine—the second for a late crop—as I like it better than the taller varieties, and I can handle the louse better. S. E. F.

Connecticut.

GRASS AND MAPLE TREES.—A reader has a contract to keep a fine grass sod on a lawn where there are several large maple trees. This is one of the most difficult things to do. The maple trees starve out the grass. Our friend thinks of trying the following grasses: For one plot, one-third each Kentucky Blue grass, one-third Perennial rye grass, one-third R. I. Bent. Another plot, one-half Kentucky Blue grass, one-half R. I. Bent. A third plot, Perennial rye alone, and another plot, two varieties of the dwarf wood grasses. Can anyone tell what grass will beat a maple tree?

Farmers' Club.

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see whether it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

Feeding Peach Trees.

S. D., Greene Co., N. Y.—Will you tell me how to fertilize my peach orchard to get the most money from this year's crop, without regard to the future of the trees? Soil is dry and gravelly and rather poor.

ANS.—Nitrate of soda is the best whip to force the last bushel out of poor soil. Tenant farmers on the last year of their lease have been known to use nitrate alone and thus obtain a good crop, though they left the soil nearly exhausted. You can use 300 pounds or more per acre of nitrate and force those trees to do their best, but if you use it alone you are likely to hurt them.

Fighting the Plum Curculio.

P. P. W., Chester Valley, Pa.—Have any of the readers of THE R. N.-Y. had any experience in destroying the Plum curculio with a solution of gas tar and water? I see it recommended.

ANS.—The notion that the Plum curculio can be kept away by bad-smelling applications is an old one, and various substances have been tested, but with uniformly negative results. The amount of gas tar that one would care to apply on foliage and young fruits would not deter the curculios from stinging the fruits for half a day, we believe. The tar would act only as a repellant, for it would not be safe to apply enough to kill the beetles. We do not believe it would give results sufficient to pay for the application. M. V. S.

Phosphate in Place of Plaster.

S. D., Oak Hill, N. Y.—I find acid phosphate much better than plaster to use in stables, so far as saving ammonia is concerned, but is there not danger of injury to animals' feet from the acid?

ANS.—We know of several farmers who use acid phosphate in this way. It gives good satisfaction. When used behind the stock and in the manure in reasonable quantities no trouble is reported. There is a waste product in the manufacture of phosphorus that is used by some dairymen. It is a sulphate of lime containing a small amount of phosphoric acid. This answers all the purposes for which plaster is used. It is a dirty brown in color and not so neat as the white plaster, but otherwise just as good. In some cases the raw ground phosphate rock or "floats" is used.

Stove for Heating Greenhouses.

A. M. A., Point Breeze, N. Y.—I am thinking of building a small greenhouse for growing cucumbers and early vegetable plants. I would not care to start it up until about March 1. Would it be practicable to heat it with an ordinary coal heating stove by having the stove at one end and run the pipe across to the other end as low down as possible, having the beds for the plants on the ground? I intend building a house about 10x25 feet.

ANS.—It is entirely possible to heat a greenhouse of the above dimensions by means of a coal stove at one end, with piping carried through the length of the house at a sufficient incline to secure a fair draft, for the few weeks of cold weather following the beginning of March. The main requisite is to prevent injury from escaping gas; therefore the stove should be a good one, and the pipe joints close-fitting. The pipe should be carried three or four feet above the ridge after it emerges from the building, and have as few angles as possible.

What Blistered the Trees?

F. P. M., Buffalo Gap, Va.—I have an apple orchard of 425 trees, which I purchased from an Ohio nursery company; 200 I set last Fall and 225 the Spring before. Out of that number I have lost 50 trees. The 50 trees which died had large black blisters on them which looked as though they were burned with fire, or as though they had been standing close to fire and been blistered; and in looking over them this Spring I find some more with blisters on them. Will you tell me what is the matter with these trees, and a remedy?

ANS.—What is the real cause of the blistered appearance I am unable to say positively, but it may be that the trees had been taken up for sale and lined out in nursery rows when they were left over unsold, which might have had such an effect, if they were rather carelessly replanted. Or, it may be that some scale insect is working on them. It would be well to send specimens to the State Experiment Station at Blacksburgh, Va., which might enable the scientists there to determine the cause of the trouble. Good cultivation may be all that is necessary to do and that is needful in any case. H. E. VAN DEMAN.

Apples for Rhode Island.

L. J. W., Summit, R. I.—Which are the best apples for market in Rhode Island? There are two distinct soils suitable for apple raising in Rhode Island; one is heavy black loam, underlaid with blue hardpan, on which apples do well if the land has a good slope. The other is a stony, gravelly formation with sandy subsoil, land which in any of the newer sections of the country would not be considered worth cultivating, and yet oak and chestnut make a rapid growth on it and make timber of the very hardest, toughest and best quality. Winter apples are likely to fall from the trees early on such land, but I think spraying will help that. How about planting Rome Beauty, York Imperial, Jonathan, Fameuse, Stayman, Wagener and Grimes? Red Astrachan pays me well. Will Yellow Transparent come earlier or pay better? Everybody around here says Baldwin, Baldwin, nothing but Baldwin, but I see other apples bringing better prices in the city. The question is, will it pay to raise apples of higher quality and spray and take the necessary care, or will it pay better to take the same care of Baldwins, and by raising a fancy quality, try to get fancy prices for them?

ANS.—I would say that both plans suggested as to varieties to plant would be better to follow than either one to the exclusion of the other. Baldwin is a good apple for the region of Rhode Island, and will be popular for many years to come, and it will doubtless pay to plant it, thin the fruit when it overbears, spray thoroughly and thus grow the very best of that variety. But there are apples of better quality that will grow and bear well in Rhode Island. All the late varieties mentioned are probably of this character. Stayman and Jonathan are less likely than the others to attain proper development. Grimes and Rome Beauty would be my choice for an extensive trial; and especially Grimes, because of its extremely high quality and rich color. It will bear regularly and heavily enough. Among the early kinds Yellow Transparent is one of the most precocious. I have known it to bear a peck to the tree when only set three years. In this respect it is far ahead of Red Astrachan. The gravelly soil is perhaps better than the tough clay for apples, but it is harder to cultivate, because of the stones it contains. H. E. VAN DEMAN.

A List of Apples.

W. M. S., Clintonville, Conn.—I intend to set out an orchard, this Spring, of about 100 apple trees. I am situated about eight miles from salt water. How about the Stayman, Sutton and Esopus, (Spitzenburg), here in southern Connecticut? Are you acquainted with the following apples; if so, which would you set out? McIntosh, Walter Pease, Fameuse, Wealthy, Wolf River, Walbridge, Sutton, Tompkins King, R. I. Greening, Pound Sweet, Roxbury Russet, Baldwin.

ANS.—For market purposes the list given is much too long, and some of the varieties are, in my opinion, of indifferent value. Stayman is not probably suitable so far north as anywhere in Connecticut. McIntosh is an apple of bright red color and quite good quality,

WRITE FOR OUR

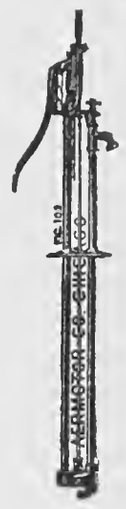
WINDMILL BOOK

We have just issued the best book ever published on Windmills. It is a 40-page book, with 125 pictures, written by the man who knows more than anyone else about Windmills. This man tells, in an interesting way, of the 5,000 experiments made in developing the wind wheel, and the results of them. He tells the vital facts that you should know before buying. You cannot buy a Windmill wisely before you read this book. Please write for it.

THE HISTORY OF AERMOTORS

The writer of this book is the maker of Aermotors. He tells you how he started 12 years ago by spending a fortune in experiments. He tells how he eventually made a wind wheel that is perfect; a wheel that gets power from a zephyr; that works when all other wind wheels stand still. He tells how he developed the modern windmill. How he invented the Aermotor features, now covered by 55 patents. How he originated steel towers, and how he perfected them. How he devised the labor-saving machinery that makes Aermotors cheaply; that makes them cost less than any other windmills worth having.

He tells how in 12 years he has dotted the earth with Aermotors. How he entered a field overcrowded with rich makers and captured over half the world's trade by making a windmill with which no one could compete. It is an interesting tale, and honest. No man who reads it will buy any windmill but an Aermotor. And a man who buys without reading it is unfair to himself. A postal card will bring it.



150 STYLES OF PUMPS

We have also a book about Pumps. It tells about the best Pumps, and the cheapest Pumps, ever made by anybody. It tells how we have reduced the cost of Pumps to one-third the old prices. No other maker of Pumps can compete with us.

It pictures and tells about 150 styles and sizes of Pumps. About Lift, Suction or Force Pumps, Three-way and Pitcher Pumps, Irrigation and Siphon Pumps, Stuffing Boxes and Working Heads. It includes every kind and style of a Pump, for hand or windmill use. It tells, too, why the Aermotor Interchangeable Pumps are in every respect the most desirable. Please write for it.

AERMOTOR CO., 1206 TWELFTH ST., CHICAGO

Write us for Windmill Book, Pump Book, or both.

but it can hardly be rated more than a family variety. Esopus (Spitzenburg) is excellent, but it does not usually bear well. It is all right for home use there. Walter Pease is only under trial. Fameuse is very badly given to scab. Wealthy is only a Fall apple, but an immense bearer and at an early age. Wolf River is large, showy, coarse and a Fall variety. Walbridge is a good bearer but not large nor high in quality. Tompkins King is tender in the trunk and drops its fruit badly, but large, showy and of good quality. Pound Sweet is not generally desirable. Rhode Island Greening is an old favorite. So is Roxbury Russet, but it is not so popular as a red variety. Baldwin we all know to be a good Winter apple in the true Northern States east of Lake Michigan, but it has the fault of fickle bearing. Sutton is new, but of much promise for the Baldwin section. If I should plant a general-purpose apple orchard of varieties that would ripen in Winter in Connecticut they would probably be largely of Sutton, Baldwin, Rhode Island Greening, Hubbardston and Grimes. The latter is of the highest quality and a rich golden color; besides being a good bearer and a healthy tree. It is a Winter apple in Connecticut, but a Fall variety in the latitude of Maryland.

Four Fruit Questions.

H. G. H., Cadiz, O.—1. Will you give a short description of the following fruits? Have you fruited the Worden Seckel pear, and can you recommend it as superior to the ordinary Seckel? 2. Is Carrie Silvers strawberry the same berry listed as Carrie, for several years in the fruit catalogues? If not, can you recommend it as superior to Haverland? 3. What can you say of Palmer's Early strawberry? Has THE R. N.-Y. ever seen the fruit or tested it? 4. I am not a plant seller, but I have been growing strawberries for market ever since 1882, having tested 123 varieties, and here are my three varieties for profit: Haverland, Ridgeway and Tennessee. If THE R. N.-Y. has anything that will beat them under ordinary culture it is just what we want. It makes me sad when I look back over the long past years and think of the money I have paid out and lost for sueh varieties as Big Bob, Jumbo, Jewell, James Vick, Bidwell, Warren, Hart, Jersey Queen and scores of others I might mention. Now it is my decided opinion that exceedingly large fruit is not the kind for general cultivation. The Ridgeway and Tennessee are large enough to stand the test, and I believe such varieties as the New York, Corsican, Edith and all the extremely large-fruited berries will become obsolete, while such a variety as the Dunlap, of which the fruit is only medium in size, will most probably occupy the front rank. Am I not half way right? If you can name a good early sort to beat Haverland, speak it out!

ANS.—1. The Worden Seckel pear is a new variety which was originated in Canada. It has been fruited by a very few of the more progressive experimenters, but as yet not on the Rural Grounds. The fruit is of much the same shape and color as its parent, the Seckel, but it is larger in size; and being fully as good in flavor and later in ripening it is thought to be more desirable than that delicious little pear. It ripens in October in New York, and may be kept until December, but in Ohio it would not be so late. 2. Carrie Silvers is a strawberry that was introduced by a New Jersey nursery firm, and has been tested on the Rural Grounds for six years past. It did very well there and proved to be larger, firmer and brighter than Haverland. It is also very vigorous and productive. It is imperfect in flower. Carrie is a seedling of Haverland, originated in Virginia and is of most excellent character. I grew it for several years beside its parent, which it seemed to exceed in both color and quality. It is also earlier. 3. Palmer's Early strawberry I do not know. 4. The point to be aimed at in growing strawberries for market depends largely upon the kind of market to which one is catering. There is no doubt that the ordinary trade calls for a medium-sized berry like Haverland or Warfield, which yield much heavier per acre than large kinds like Marshall or Sharpless, and bring about two-thirds as much per quart as the very large ones. But in the fancy market the difference is in favor of the large kinds. Excelsior would be a good kind to test, as it is earlier than any of those mentioned, and a good shipper.

THINGS I HAVE TRIED.

The old-time method of brushing peas, with which the older boys are disagreeably familiar, has become a back number. I now drive four-foot stakes three paces apart after the peas are planted, and then tie the top and bottom wires of the two or three-foot light chicken-wire fencing firmly to them. This serves the purpose, is durable, and best of all can be put up quickly during the usual hurry of Spring work. A decided advantage of this method of supporting the peavines is, that after the peas are picked, tomato seed can be planted three feet apart in the row, or small plants may be set, and a late maturing crop of tomatoes for Fall and early Winter use can be grown. The wire netting to which the vines are to be tied, obviates the use of a stake at each plant.

The Satsuma plum tree in the chicken yard, the ends of whose branches were disposed to humble themselves by bending nearly down to the ground, had to have this tendency checked. This was done by ripping open some light, inside coffee sacks, cutting them into strips six inches in width and tying enough of them together, to make, when twisted, a soft rope that could be passed entirely around the branches of the tree, and after they were drawn together sufficiently, the ends could be firmly tied. When the trunk of the tree was about two inches in diameter two of these ropes were sufficient. The ropes have now rotted off and there seems to be no further need of them.

My plan of manuring the garden in the Fall and spading or plowing the land up into ridges, which are four or five feet from center to center, has this Spring, as usual, put the soil in the finest possible condition even though the land is not underdrained. These ridges run from east to west. By leaving the north half of them intact and opening a deep furrow on the south side, I have a sheltered, warm place for early potatoes, peas or other early vegetables. I know of no method that involves so little expense or, in the absence of hotbeds and other conveniences, that is so productive of good results. The principle of filling the soil with well-rotted manure each Fall and ridging up the land to be acted upon by the Winter frosts, is one, which, if once adopted, will be indefinitely continued, especially on clay soil.

One of the most successful plans in this locality, and which would be likely to prove still more advantageous in the cotton-growing States, is the barrel method of growing cucumbers and Summer squashes. As soon as the soil in the garden can be worked, take a flour or apple barrel, remove the upper head only, and bore a three-quarter or inch hole in the center of each stave midway from the bottom to the top of the barrel. Wherever the soil is the poorest I dig a hole deep enough to have the augur holes six inches below the general surface of the ground when the barrel is set. I now fill the barrel nearly full with stable manure and pack it down firmly, not forgetting to add an occasional layer of coal ashes and chicken manure from the poultry house. Next, enrich the soil about the barrel to a width of 12 to 14 inches, make it fine and plant the seeds. Begin the subsequent irrigation of the young plants by filling the barrel nearly full of soapsuds and rinsing water each week. The liquid manures flows out of the holes and comes in direct contact with the roots of the plants. This has resulted so far, in protecting the young plants from insects and producing an abundant supply of fine, crisp cucumbers. The barrel for the Summer squashes is set at the other side or end of the garden and treated in the same manner. This supplies the table with squashes until the frost kills the vines. J. W., JR.

Glencarlyn, Va.

For the land's sake, use Bowker's Fertilizers. They enrich the earth.—*Adv.*

A
Potato Bug
is getting to be a hard bug to kill. So many poisons have been tried on him, he has become pretty nearly "poison-proof," but **Bowker's**
"BOXAL" WILL KILL HIM
and at the same time **prevent blight of vines and rot of tubers,** thus serving three purposes. We have many testimonials showing the truth of this in our catalogue of Insecticides which also contains **a hand book of injurious insects and plant diseases,** and how to fight them. 40 pages, fully illustrated. The Cornell Reading Course.

Edited by John Craig, Professor of University Extension, and Editor Farmers' Reading Course, Cornell University, Ithaca, N. Y.

INTRODUCTION.

Many of THE R. N.-Y. readers know about the Cornell Reading Course for farmers. This is a correspondence course in agriculture. It is a development of the last five years. It is significant of substantial progress in farming. The fact that over 25,000 farmers of New York State think it worth their while to bother with the lessons—nay, more—study them carefully, indicates that the movement is growing, and that the old-time prejudice against "book farming" is gradually disappearing. The question and answer department of a school of this kind must be very instructive. While each farmer looks on his own difficulties as being peculiar to himself, they are in fact but a reflection of his neighbor's troubles emphasized and colored by local surroundings. Interchange of thought and experience therefore cannot fail to be valuable. This column will be devoted to answering questions and exchanging experiences in fruit and gardening matters. THE R. N.-Y. has always given a prominent place to horticultural questions, and it is fitting, and also a matter of self-congratulation, that we find ourselves able to use such an excellent medium for exchanging confidences. The fruit interests of the State are constantly enlarging; new problems are appearing, old problems recurring under new guises, and the fruit grower finds that the price of success is industry, common sense and vigilance. A few readers will always find in the queries and experiences old material, but they will be new and instructive to the many. Come into the circle, friends, and turn the searchlight of experience and science on dark places in farm practice.

McPike Grape.

Do you know the McPike grape? Describe it and give your opinion of its value.

Medicine Lodge, Kan. J. L. B.

In August, 1900, while connected with the Iowa Agricultural College, I made a special trip to the grounds of the originator of this grape, H. G. McPike, Alton, Ill. Mr. McPike informed me that the grape was grown from the seed of Worden. It resembles the parent in foliage and color of wood. The fruit is also like Worden in color and form of bunch. The berry is much larger, fully as large as the one-time famous Eaton. Most of the McPike vines in the originator's vineyard are on Concord roots. They were crown-grafted; they were fruiting heavily at the time of my visit, both on this root and on their own roots—although there were comparatively few vines in the latter condition. The original vine, eight or nine years old, is still standing in Mr. McPike's vineyard. This variety appeared to me to have unusual promise. Mr. McPike's vineyard is favorably situated on the Missouri River bluffs, on well-drained loess soil. The possible weak points about this variety, as they appeared to me, were thinness of skin which might injure its shipping qualities and weakness of growth. Now the latter character was not apparent, it was only suggested. And the foliage in every instance was perfectly vigorous and almost entirely free from fungous disease.

The Neglected Orchard.

I have an orchard of Greenings and Baldwins 25 years planted. It is in sod, has not been cultivated or sprayed, and is not giving satisfactory returns. What course of treatment would you recommend?

New Hurley, N. Y. H. M. G.

If I had this orchard I would plow it as early as possible in the Spring. Throw the sod from the trees, and as you approach the trees plow lightly. Soon after it is plowed I would, with a disk harrow, cut up the sod as thoroughly as possible. Where the plow would not reach, the sod should be removed with a mattock. After the disk harrow is used, the work of keeping the surface free of weeds and in a fine state of tilth can be best accomplished by using a smoothing harrow. The trees should be sprayed with Bordeaux Mixture and Paris-green before the buds open. Two or three applications of the same mixture should be made at intervals of two weeks after the blossoms fall. If the trees need pruning, it could be done any time between now and the beginning of active growth. I would not prune very heavily at this time, merely removing such branches as are weak or are interfering with each other. At the close of the season's growth, which is usually about the first of August, I would seed the orchard to Mammoth clover. If the ground has been kept in a good state of cultivation, sufficient moisture will have been preserved to ensure with favorable weather a good clover catch. This clover will form a cover for the ground and will return, when plowed under next Spring, a large amount of nitrogen. It also makes a good ground cover during picking time.

Deep Versus Shallow Cultivation of Beans.

The raising of beans has become quite an industry in this part of the country. There are various opinions in relation to cultivating them. Some say that two cultivations are better than more on account of destroying the roots; others think they need more. Late cultivation does injure the roots somewhat. W. F. H.

Brockport, N. Y.

In dry seasons the success of the bean crop, like corn or other hoed crops, depends largely on the amount of moisture in the soil. Moisture can only be preserved after the crop is planted, so far as man's efforts are concerned, by thorough tillage. I believe that we can cultivate so deeply as to injure the roots of the plants, but thorough cultivation does not necessarily mean deep cultivation. Surface tillage is nearly always preferable to deep tillage. If you can use an implement which will just stir the top of the soil and preserve the dust mulch, there can be no question about the benefit of this kind of tillage in dry seasons, but if large shovel cultivators are used, and run deep, then unquestionably the cutting off of the feeding roots of the plants will result in direct injury and lessened yield.

Getting a Catch of Alfalfa.

I have a piece of clay loam (rather heavy) which was well manured and planted to corn last year, which I would like to try with Alfalfa this season. It is not just the best soil for the crop, I expect, but it is the best I have. What do you think I would best use for a fertilizer to get a good stand? The soil is not sour.

Neills Creek, N. Y. O. W. A.

If the piece of land you describe gave you a good crop of corn last year, it ought to be in good condition to give a good catch of Alfalfa this season. If you plowed it last Fall, I would work it with a spring-tooth or disk harrow as early as possible this Spring, and get the Alfalfa in while there was plenty of moisture in the ground. The Winter snow has been heavy and the Spring rains have been abundant. Our soils are soaked with moisture, and we ought to hear small complaint this season regarding unsatisfactory stands of grass and clover seed. While it does not seem to me that this soil needs anything particular in the way of a fertilizer or amendment, it might be desirable to dress it with a superphosphate at the time of seeding; 300 or 400 pounds per acre would be a liberal application. I would certainly use not less than 15 pounds of Alfalfa seed to the acre.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee

Mr. W. H. Kennison, of Brownville, Me., writes: "I gave my potatoes three sprayings with Bowker's 'Boxal.' As a result, I got one-third more potatoes than I have had for four years previous."—*Adv.*

HOPE FARM NOTES.

WET GOODS.—Easter Sunday found Hope Farm like a great sponge. We started the plow on April 2—plowed the chicken yard and a few rounds in the orchard, and then had to make for cover. The rain fell steadily for the rest of the week. It would pelt hard until all out of breath, and then drizzle while getting ready for another round. Young rivers poured down the hills, and the roads were great beds of deep mud. It was hard to watch that flood of water and realize how it kept our work back. The oats ought to be in, and yet it was impossible to turn a furrow. The grass and grain stood up and jumped as the rain fell, but we did not seed half as much as we should have done last Fall. The trees were thriving and the wells and springs were filling up, but we couldn't get half the comfort we wanted out of that. So when Easter opened with more rain—well, we didn't like it. The Madame and Hugh went to church, but they didn't have any new bonnets or clothes to spoil, and that was a small satisfaction at least. In the afternoon I tramped through the mud over the farm. I tried to whistle, and say: "This is just the thing for our peach trees—planted on that Stringfellow plan!"—but the words nearly stuck in my throat when I saw how the water had gashed the hillside and washed the grass seeding. Verily, man is hard to please. In drought he prays for rain. When Nature pours rain with a liberal hand he growls. When he gets weather just to his taste how often does he give thanks for it? Mighty seldom, I fear.

FARM NOTES.—The first run of the incubator gave us 103 chicks. We put 200 eggs in, but only about 130 tested fertile. They were purchased eggs—Wyandotte and White Leghorn. The Leghorn eggs proved the better. This hatch doesn't size up very well by some of the reports we read about—but we give the facts. A hen sitting on 15 of the same lot of eggs hatched nine chicks. . . . We are often told that it is possible to sow rye very late in the Fall and still get a fair yield. We have about two acres which were sown November 1. The stand is fair, but the plants are small and spindling as compared with the earlier-sown grain. This rye may come to the front yet, but it ought to go in earlier. . . . The Crimson clover, seeded with the rye after early potatoes is fine. The rains are bringing all grass and grain out. This Crimson is particularly good. It will be cut with the rye for hay or green fodder—in fact, I expect to cut all our small grain this year for hay. The oat hay this year was so satisfactory that I think it paid better than the grain and straw would have done separately. . . . We are still feeding cabbage and yellow turnips to the pigs. This cabbage was kept in an old chicken house. It froze solid, and is not salable in the market, but a good proportion of it is fit for the sows, and they eat it readily. We boil the yellow turnips and mix them with bran and middlings. . . . I still think that we kept our Berkshire sow too fat, but we do not purpose to repeat the mistake with the others, and they are living on what they evidently call short commons. They have plenty of raw cabbage—and a fair feed of boiled turnips and bran. Corncob ashes are on hand for them. . . . I do not intend to sow many of the much-praised fodder crops this year. I have yet to find any late-sown crop that will make more good fodder to the acre than our Rural Thoroughbred corn sown in drills. When used after oats or other grain, or following a meadow, it will make an abundance of feed, and rye can be seeded in it at the last cultivation.

TOO MUCH FAT.—Side by side in our barn stand two heifers which seem to teach a lesson in feeding. They are sisters—daughters of our old Jersey—their father being a Holstein. The older one is fat and beefy-looking. Her neck is heavy and her back and quarters are thick and coarse. The younger heifer is thin and fine—a picture of the old cow. Breeders tell me that sisters will frequently vary in this way. In fact, we see many cases of such variation in human families. I think, however, that in this case the trouble is largely due to feeding. I think the older heifer had too much food, so that during her early life she took on the beef or fat-making habit, which made her coarse and gross. The little one has not had so much milk, and has had to hustle more. She will make the better cow of the two. No use talking, many of us feed too much fat and foolishness to our young stock—brute and human—so that when the whip of necessity urges them on to do their share of the world's work they have flabby flesh or fooling habits when they should have muscle of body and brain. The trouble is, too, that we feed foolishness to the child out of our own example! In crossing two breeds as we did in the case of these heifers we cannot tell which parent they will most resemble.

KEEP GOOD NATURED.—The wet weather is bad enough, but it would be worse if we let it dry up our faith in the outcome. Some folks seem to think that the wife and daughters are responsible for the weather, and they go into the house and growl like bulldogs at the women folks. I wish the farm women all over this country would turn on such fellows and make them understand that weather growls are for outdoor consumption. There is far more sense in trying to be cheerful and keeping on top of the weather, than in letting it ride you. Why, we might work ourselves into the belief that we are worse off than other folks, when thousands of farmers are wetter than we are, and further behind with their work! Here is a man from a section of New England where on April 3 they had five inches of snow! Yet he comes forward with the following:

At present we have two horses, four cows, two yearlings, four calves, 45 sheep, nearly 200 hens, a brood sow, a pig, and a duck. This duck, though she comes last on the list, is by no means the least among us. She has a record of two eggs a day, and is in every way a bird of superior qualities. She rejoices in the name of "Knox," for two reasons: First, she is named after a friend, and second, she just "knocks the spots" off all the other ducks hereabouts. Last year this duck formed a strong attachment for a White Leghorn rooster; in fact, the admiration seemed to be mutual. This unusual friendship tempted me to perpetrate poetry.

A PARADOX.

A cute little duckling called Knox
Fell in love with a rooster named Cox;
They were wedded one day
In the regular way;
And now they raise chicklings by flox.

R. W. R.

I wish I could write poetry under such depressing circumstances! You will see that "Knox" keeps right on doing her duty through rain or shine. Would that more of us had oil on our faith, so that wet weather would drop off without taking the starch out.

ANOTHER WINTER JOB.—Suggestions for new jobs come rolling in. Here is a good old job in a new light:

I see at Hope Farm you want a side line that will keep you busy in Winter. I do not think much of witch hazel, broom making, mail order, etc., but if you keep a dairy and retail your own milk to a medium class of people who take only pints and quarts I guarantee you will not only have all the work you want in Winter, but work in Spring, Summer, Fall and Winter; Fourth of July, Christmas, Sundays and everything else thrown in. I speak from experience; have about 25 cows and retail about 130 quarts of milk daily to that class of people, which means that I must climb in and out of the wagon over 100 times in a day. We try to raise enough roughage for the 25 cows, three or four heifers, a bull and four horses; keep a few pigs and hens, and raise three acres of potatoes. We do not take anything to make us sleep at night. W. E. G.

I know that by experience. I once drove a milk wagon and milked my 20 cows a day. You don't need any "knock-out drops" when night comes if you are brother to the cow. There are many worse sisters in this world, however, than old bossy. I am not hunting a job for the mere sake of working, but we all know that Winter is the dull season on most farms, and I would gladly make it profitable for all our folks if possible. H. W. C.

THE experience of practical painters has proved that thin coats of paint, well brushed out, give the most durable results. Because of its great spreading capacity and its extreme density, Pure White Lead is the pigment best adapted for this method of painting.

The brands shown in the margin are genuine *"old Dutch process" White Lead*, the best it is possible to manufacture.

For any color or shade required, use NATIONAL LEAD COMPANY'S Pure White Lead Tinting Colors. Pamphlet sent free upon application.

National Lead Co., 100 William Street, New York.

Twin Pipe Sprayer.

The pipes are spread so as to spray a greater width than others.

Dewey Sprayer.

The only hand sprayer that will make a mechanical emulsion of kerosene and water. Simply fill small reservoir with oil, large with water. Can be used without oil for other purposes.

Jumbo Duster.

To operate from a wagon, weighs about 30 pounds. Will dust any dry powder, Paris-Green, etc., on tall trees, cotton, potatoes, etc., spreading powder from 12 to 15 feet wide.

Churn Sprayers.

Work by compressed air, and throw a continuous spray. Distribute oil and water, producing a mechanical emulsion. May also be used with water and Paris-Green or other insecticides. 1, 2 and 10 gallon sizes.

Champion Duster.

For dry insecticides. For farm, garden, orchard, tobacco field. Will green two rows at once as fast as a man walks.

Little Giant Duster.

Smaller and differently constructed from the Champion. Dusts any dry powder, two rows at once.

A full line of circulars furnished on application.

AGENTS WANTED.

LEGGETT & BROTHER, 301 Pearl Street, New York.

Buy a Planter

THAT PLANTS all kinds of corn, for all purposes, on all kinds of ground and in any soil and save time, labor and money. The SPANGLER CORN PLANTER fills the bill to the letter. You always know when it's working properly because you can see the corn on its way to the ground. With or without fertilizer attachment. New device for sowing peas, beans, ensilage corn, etc. Also make Spangler Broadcast Fertilizer Distributer, Spangler Single Row Fertilizer Distributer, Spangler Low Down Grain and Fertilizer Drill. Write for circulars.
SPANGLER MANUFACTURING CO., 505 Queen St., York, Pa

Barns of Plank save timber and cash. Best, cheapest, strongest. 4,000 in use. Book for stamp. SHAWVER BROS., Bellefontaine, Ohio

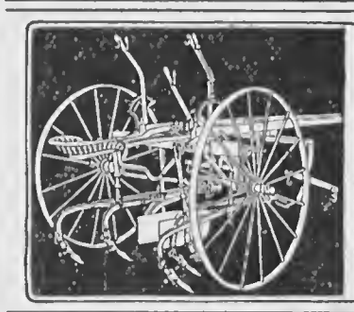
STAR PATTERN BILLINGS **Planter and Fertilizer**

Is the latest, and it drops at twelve different distances.

For CORN, BEANS, PEAS and BEET SEED.

If you want them, we furnish Marker and Trip Attachment for rowing both ways. Send for Circulars.

AMES PLOW CO., Boston and New York.



CULTIVATOR QUALITY

both as to construction and ability for working row crops, finds its complete embodiment in the

KRAUS Pivot Axle CULTIVATOR

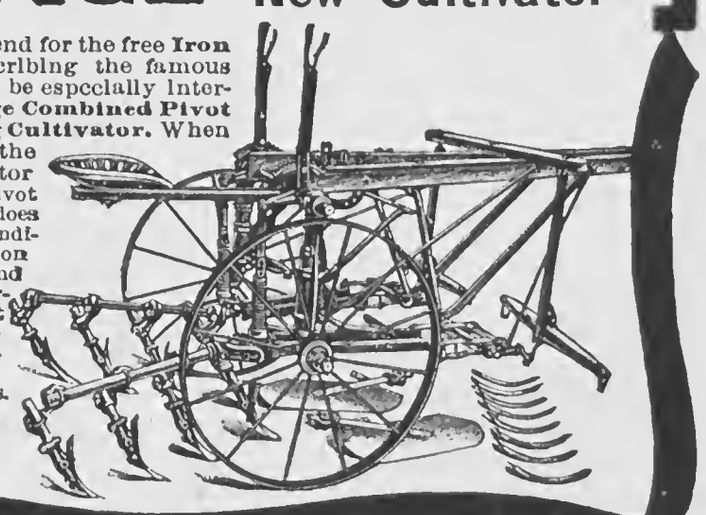
The pivot axles make it the easiest to guide and handle, moving the wheels and shovels simultaneously. It will stick to the steepest hillside row and not crowd out the plants. Convenient levers for handling the gangs. Center lever spreads or closes gangs to suit wide or narrow rows. Two, three or four shovels on each gang. Made pin or spring hoe and spring tooth. Full description in our free catalogue. We also make the Carpo Walking Cultivator.

The Akron Cultivator Co. Dept. D, Akron O.

IRON AGE News about the New Cultivator

Progressive farmers who send for the free **Iron Age Book for 1901**, describing the famous Iron Age Implements, will be especially interested in the novel **Iron Age Combined Pivot and Fixed Wheel Riding Cultivator.** When used as a fixed wheel it is the best Fixed Wheel Cultivator you can buy. When used as a pivot wheel, again it is the best. It does perfect work under every condition that confronts the farmer on any soil or surface, any crop, and rows of any width or irregularity. The book that describes it tells about all the Iron Age Seed Drills, Wheel Hoes, Riding Cultivators, Potato Planters, Horse Hoes and Cultivators.

BATEMAN MFG. CO., Box 102, Grenloch, N. J.



Ruralisms

NOTES FROM THE RURAL GROUNDS

Rambler Roses in Winter.—Since the introduction of that most distinct and valuable hardy rose, Crimson Rambler, which is understood to be a climbing form of the Chinese Rosa multiflora, often catalogued as R. polyantha, many seedlings and hybrids from it have been grown with a view of getting something still better, or at least sufficiently distinct to make a good companion. Several hundreds of cross-bred Crimson Ramblers have been raised on the Rural Grounds; beginning in 1894, the Rambler blooms being pollenized with almost every species and variety that could be secured. While some very pretty things have turned up none show sufficient improvement to warrant propagation except one rather dwarf specimen which produces dense clusters of deep crimson flowers, much more double, and in every way superior to the type, in the opinion of those who have seen it, but it has not been long enough in cultivation for its real value to be determined. Several new single and double-flowered seedlings of Crimson Rambler have lately been announced in Europe, and will doubtless soon be offered here. Helene is a German production of this character, and has been grown in this country for the last two years. It is certainly valuable, as it is as strong a grower as its parent, but less rigid in outline. It seems to be entirely hardy in this latitude, and possesses better foliage than Rambler, being more resistant to mildew and insects. The canes are practically thornless; a great advantage when planted about the house. The flowers are larger than Crimson Rambler, and are produced in immense clusters, almost covering the plant. The color is a blush rose with a violet tinge. They are very double, but the bright yellow anthers show through, making a pleasing contrast. The buds are bright carmine. We have just tried Helene as a Winter bloomer, and find it rather more free in bloom under the same conditions than Crimson Rambler, but the flowers are scarcely as durable and the color effect is naturally less striking, though this defect is offset by a delicate perfume, quite lacking in the parent Rambler. The Yellow Rambler, formerly known as Aglaia, has also considerable fragrance, and is really very attractive when in bloom. The buds are bright yellow and very pretty, but the flowers open quite pale. It is much less inclined to bloom under the Winter forcing treatment, and we have only been able to secure a single bloom in two attempts with strong, well-established plants. It blooms very well outside, but not until it has made considerable growth. The White and Pink Ramblers are also acceptable for outdoor planting where there is plenty of room, but like the yellow one, they do not force well, as they must make strong wood before blooming. They are also of Multiflora parentage in some degree.

Crimson Clover and Crab Grass.—Notwithstanding the severity of the high February winds, and the frequent sharp freezes following, the several small plantings of Crimson clover on the Rural Grounds are coming on vigorously, but the best lot is in a rather neglected strip where Crab grass was allowed to overtop the young clover during the Fall months. It was planned to pull the grass out before it seeded to any great extent, but other work prevented, and the benefits of protection are now plainly apparent. It is quite certain we have not learned sufficiently to appreciate the possibilities of this ever-present and most energetic exotic grass. In a previous number of The R. N.-Y. (page 770, November 17, 1900) an account was given of the preference some New Jersey farmers have for a covering of Crab grass to prevent the blowing away of their light soils during Winter. Crimson clover does not hold on sufficiently, and is too uncertain in starting during dry Autumns to be depended on in this locality, and Crab grass, while an effective Winter cover, does not add appreciably to the fertility of the soil. If it is practicable to combine the advantages of both with additional protection for the clover by sowing the latter early on ground naturally well seeded with Crab grass it is easy to understand the benefits likely to arise from the partnership.

Geraniums as Decorative Plants.—Many beautiful varieties of Zonal Pelargoniums, popularly known as geraniums, are introduced every year, but make little progress in cultivation, as they are not able to endure our severe climate when treated as bedding plants. In other words, they are not "sunproof," and in consequence are quickly discarded, but this is too great a loss, as they can usually be grown to great perfection in the conservatory or window garden. Fig. 119, page 287, shows a type of bloom of this large-flowering, decorative class as grown by Henry A. Dreer, Philadelphia, Pa. The variety is Hall Caine, cherry-red in color, with florets 2½ inches across. The coloring of some of the new kinds is wonderfully delicate in the light shades and vivid in the darker tints, while the habit of plant and form of truss leave little to be desired. So many new ones are coming out that it is not desirable to describe varieties which may be quickly superseded, but all now offered seem worthy of trial.

Care of Young Rose Plants.—Plants of Ruby Queen rose are now being mailed to new subscribers, and to those who failed to get it last year. While Ruby Queen is one of the hardiest of roses when established these young plants are mailed directly from the warm greenhouses, where they have been propagated during the Winter, and should have some special care and protection when received. The plants as sent out have been grown in two-inch pots, and it is best to repot them in a new three-inch pot, if procurable, using light, rich soil, well worked among the roots and firmly packed, leaving a half-inch space at the top to receive water. Soak the earth well, and place the pot in a light window, out of direct sunlight, until the plant straightens up. Keep the soil fairly moist, but never sodden, and by the time it is safe to plant outside it should be well-established and in good condition to bear the change. When a small pot is not at hand a convenient substitute may be found in a condensed-milk can, with the bottom plentifully pierced with holes for drainage, though there is more difficulty in getting the plant out later than with the conical pot. If a greenhouse, hotbed or cold frame is available the rose can be cared for with the other plants more easily than in a window, as it will require less special attention. If received after outdoor plants began to grow the Ruby Queen rose may be planted directly where it is to bloom, watering well and protecting slightly from chilly nights and harsh winds until a new growth starts. No rose came through the past Winter better on the Rural Grounds. Our solitary plant is clean and bright, and the buds are pushing vigorously this first week in April. It had no protection whatever, and is so placed as to receive the full sweep of the bitter north winds.

Live Stock and Dairy

THE BREEDER'S WAYSIDE.

Feeding Pigs Without Milk.

We have a dairy farm of 21 cows from which the milk has formerly been made into cheese, the whey being fed to hogs. Last year the milk was sold outright, and the tenant states that he cannot raise hogs profitably (if at all) without the whey. For grain, corn and oats are raised on the farm, and we usually buy some middlings for the young pigs. We have a good hog house. Will you inform me what to feed the hogs in the absence of whey, and what the milk should sell for, to make it less profitable to raise hogs than to feed all the grain to the cows when dressed pork is worth seven cents per pound? When we had whey to feed the hogs, the tenant probably sold 1,000 pounds of pork, and we thought it well worth while to keep hogs. M. E. H.

Herkimer Co., N. Y.

I should say something was the matter with either the kind of pigs fed, or the man feeding, rather than the feed used. Not one pig in 10,000 ever has had a taste of whey, and while it has some value as a food, that value is slight. Skim-milk and buttermilk are very valuable adjuncts to pig feeding, as the casein, which goes into cheese, is very valuable in food constituents. For an extensive feeding experiment with pigs last year, where a mixture of cornmeal and shorts, half and half, was fed, or of shorts and hominy fed in the same proportion, the writer produced pork for as low as $2.87 per 100 pounds, and no milk or whey was fed. Sixteen pigs were fed, and from January to late in June, and during all that period, the highest cost of production was $3.04 per 100 pounds. Our feeding was of course done with judgment, and we had good pigs, but our results are not at all remarkable. Yet these figures show these pigs to have been fed with profit when pork was quoted at the lowest figures usually listed. For Chicago pork has now climbed to over $6 per 100 pounds. Think of the profit in feeding pigs at that price!

If the pigs are kept dry and clean, and in a place not too warm or too cold, and not drafty, and are from fairly good stock, and fed by a man with reasonable judgment, they should make a satisfactory profit, with pigs at $3.50 to $4 per 100 live weight. The tenant who says he can't feed pigs profitably without using whey, stands alone in a class by himself. Most other feeders can. Without the whey, cornmeal and shorts will probably be your most available food. Fine bran may be used in place of shorts, but it is not so good as shorts, middlings or ship stuff. So far as selling the milk is concerned, I should continue selling it. Skim-milk is worth as high as 20 cents per 100 pounds for pig feed, and if you can skim some of the milk and sell the cream, and feed the milk to the pigs, you will have a valuable addition to your feeding stuffs. But this is not really essential, unless to young recently-weaned pigs, or sows suckling pigs. You certainly can't afford to feed them whole milk.

C. S. PLUMB.

"ONE OF THE MILLION."

A Road to Successful Farming.

A recent article in THE R. N.-Y., written by Prof. Roberts, was very interesting to me. This is probably due to the fact that I am one of those "in competition with the million." In June, 1898, I finished a four-year course in agriculture at the New Hampshire College. At that time I was confident that there was money in farming, and engaged myself in practical farm work at once after leaving college, having taken the home farm for two years in company with a younger brother. The lease began the first of May previous to the 1898 commencement. We went into potatoes and dairying. The first season we had nine acres of potatoes and 17 cows. In the Spring of 1899 we leased another farm, put in 20 acres of potatoes, and milked a few more than 40 cows on the two farms. About these these two years I will say but little save that we made only fair day wages. These returns were not satisfactory. Nevertheless I was still confident that with better cows and cheaper roughage better returns were possible. Consequently I again leased the last-named farm for two years. The agreement, among other things, states that the owner should furnish 24 good cows and build a silo. I got a set of dial-spring milk scales and have since been keeping individual accounts with the cows. The first year is not up until May 1 next, but the figures already are sufficient to show wherein the majority fail to make money in dairying. Estimates have been made for the full year based on what has already been done.

The cows were picked up about here, and are generally considered to be good ones. Not over one-half of the number will stand my figuring and return any profit whatever. They have been well-cared for and fed in a general way according to scientific principles of feeding. The hay and silage have been supplemented with nitrogenous mill feeds. Most of the Winter the cows have had 10 pounds of hay, 30 pounds of silage and four pounds of meal composed of mixed wheat feed and cream gluten, equal parts by weight. Cows in full flow of milk get eight pounds of this mixture instead of four. The above ration was found to be much more profitable than the following, which was fed for a time the first of the Winter: 20 pounds of hay, 30 pounds silage and 1½ pound mixed wheat feed. It is astonishing how the scales, Babcock test and a few figures will throw light on a subject. One soon learns to tell by a glance at the record of a cow whether she is being fed at a profit or a loss. A short time since it was noticed that one cow was being fed as above at a loss. Her grain feed was cut down one-half, and she then failed to pay her way, but the deficiency was not so great. This cow is not in the herd at present. Last Spring there was placed at the head of the herd a registered Holstein bull with a double line of good ancestors. This was done with a view to raising up some better cows. The result thus far is satisfactory as the calves are nearly all extra good ones.

I am making a specialty of raising potatoes for seed, as the land is naturally adapted to potato growing. In this branch there is one departure from the ordinary. Each hill is dug by itself, and potatoes are selected only from superior hills. There are many things about both cows and potatoes that are of much interest. Unless the writer is very much mistaken, this is one of the roads leading to a more profitable system of farming. BURTON A. CORBETT.

The Chicken Yard.

EARLY LAYING PULLETS.

How Grown in a Cold Country.

For two reasons I try to have my pullets begin laying early, having found that yearling hens rarely get over moulting in time to lay before cold weather. The first reason is that Fall and Winter eggs bring the highest prices, the second that from pullets which have laid well all Winter I can select my eggs for hatching, and secure strong fertility. One must begin with the hatching to accomplish anything. The chicks must be March or April hatched, whether by hen or incubator matters not. I, however, have never been fortunate enough to get mine hatched before the middle of April and oftener the end of the month. The eggs set must be from vigorous, healthy stock, and of as good a strain of layers as is procurable. When the chicks are hatched, if by a hen, then the trouble begins. No need of feeding them first thing. If they are not fed for 24 or 36 hours they will be all the better for it. If brooder chicks it is much easier to attend to them. For the first few days, or even a week, I feed stale bread soaked in water and squeezed out so it crumbles. Then gradually give rolled oats, wheat, millet, johnny cake and dry bran. Have coarse sand accessible at all times. One lot of chicks I gave no drinking water till they were two weeks old. Late-hatched ones, however, can have water when a day old. Chicks should be fed what they will eat up clean four times a day for the first two weeks, then three times till two months old.

Young chicks should be kept warm and free from lice. If hatched by the incubator the matter is very easy; having been free from vermin at first it is simply a question of keeping the brooder clean. If taken care of by the hen it is much harder, as the hen and chicks will have to be dusted with some lice powder every week or so. Chicks should be kept warm, especially in early Spring If brooder chicks they must be taught to run into the brooder, which may be much cooler than at night. With brooder chicks the mistake must not be made of getting them used to too warm an atmosphere at night, as it makes them more susceptible to cold when out doors. At about four weeks I began to give a mash of one-quarter middlings, one-half cornmeal and one-quarter bran mixed with skim-milk or water for one feed a day, and cracked corn and wheat several times a day. At first chicks had only a limited range, but as they grew older they had the run of a nice lawn, and later the gardens, somewhat to their detriment.

When the chicks were about 10 weeks old I fed only one meal a day, and that merely to keep them tame and in the habit of looking for feed from the house. All table scraps were thrown out to them, and as they had access to the barnyard and barns they did not lack for grain feed, and gathered up much of what would otherwise be loss. Water was placed where they could get at it at all times. A very good drinking fountain for young chicks was made from baking powder cans notched a little on one side and set into a saucer or tin-pail lid.

One year I was forced to buy about 50 April-hatched chicks when they weighed 1½ to two pounds apiece. They were put into the barn to sleep, as we had no suitable house for them. From that they began following the cows to pasture, and particularly into a small marsh. Here they found plenty of grasshoppers, and I never had such healthy chickens, or any that grew so well as they did. When I began to feed corn in the Fall they had to be taught to eat it. About the last week of September I begin to feed an evening feed of grain, usually corn, and as the days get colder a morning mash of middlings, ground corn and oats. Pullets and cockerels roost in trees till the cold weather comes on, when I usually succeed in capturing them and putting them into the henhouses. For the past two years this has been about the middle of November, but it is far the best to have them in Winter quarters about November 1. My chickens were incubator and brooder chicks the past year, and so tame that the handling necessary to get them from roosting places and into coops did not disturb them in the least, for the pullets began to lay the next day. I had found an occasional egg at odd times for a week before housing, so that they were ready to lay by the middle of November. When I get them housed I like to feed whole wheat for one feed a day, and the mash is then composed of one-half middlings, one-half cornmeal and oats ground together with any kind of scraps, vegetables or whole grain as a relish, and sometimes I add a little oil meal to the mash. We usually raise oats and wheat together, cutting and curing when ripe, then stacking till Winter, when it is thrown into pens for scratching material. The way to get Winter eggs, I find, is to feed regularly, keep plenty of fresh drinking water or skim-milk, grit and wood ashes containing charcoal before them at all times, and give them plenty of scratching to do.

MRS. G. L. ROSS.

Wisconsin.

A CITY MAN TURNS FARMER.

PART VI.

When the peach trees came I had abundance of room to spread out the roots and had to half fill the holes with good loam to prevent getting them too deep. Of course all this was fine for the young trees, and they made a growth in the next three years that was the astonishment of all who saw them. An old fruit grower from New Jersey said he never saw it equaled. Branches six to seven feet long, five-eighths to three-quarters inch in diameter as the result of one season's growth were common. I planted sweet corn and garden stuff among the trees, and that clover sod, with the cultivation, did the business. I was very proud then of my trees, and used to take pains to show them to callers; now I know that a much smaller growth would have been better for the trees. Although I pruned heavily, cutting away half of each season's growth, ice storms in Winter have pruned still more heavily, splitting some of the trees down to the ground, and breaking great limbs off others, until there are not 20 whole trees left out of the 35. Still, although last year there was only a partial crop of peaches, we got about 50 baskets from those six-year-old trees.

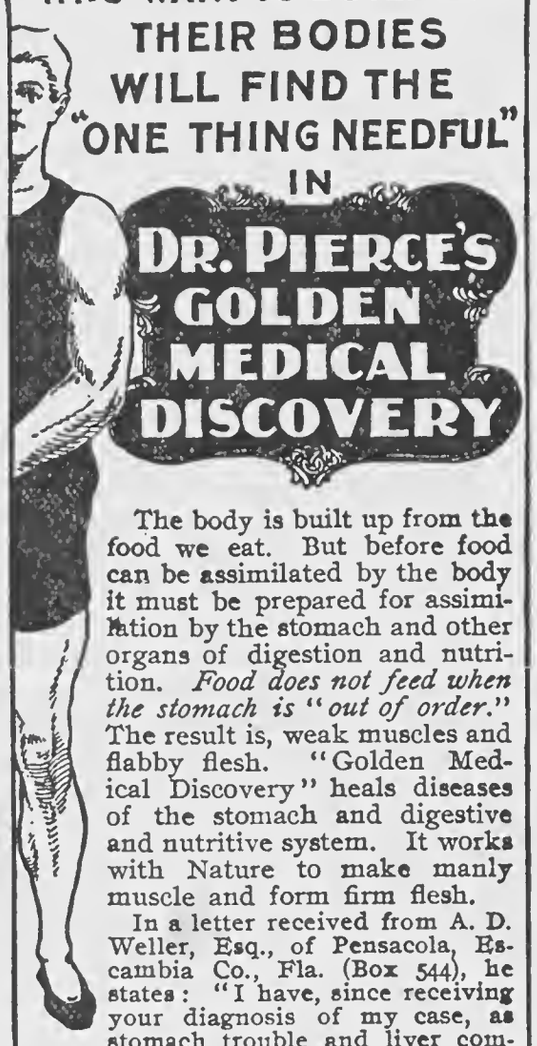
We had planted some potatoes on a small piece at the bottom of the same lot, which had been cultivated several years, and when they came up and got big enough to hoe, a rainy season set in, and the ground was too wet to work for a couple of weeks. When it became dry enough, and I started to hoe them, not a potato plant could be seen, nor a square inch of bare ground. The whole piece was a mass of charlock, a weed with a large leaf something like turnip. Cultivating it was out of the question, as it was impossible to see where the rows were. I had to pull the weeds with my hands until I could find the potato rows, and then it required slow and cautious work to hoe them. It was a back-breaking job, and I have never allowed a crop to get away from me like that since that first experience.

Our first calf was a wonderful creature. How the children would run out the first thing in the morning, and as soon as they returned from school, to fondle and pet little Buttercup, as they named her! Nothing was too good for her, and we spoiled her with good feeding, so that when she was two years old, and began to give milk, she was a fat beefy creature with a neck so thick that I had to widen the space in the stanchions two inches, although it was wide enough for any of the cows. When Buttercup was about eight weeks old we had her tied out where she could get grass and run as far as the rope would allow. One day she got loose, and went down the road with about 30 feet of rope trailing after her. As it chanced, my wife was the only one who saw her, and she went out and got hold of the rope when the calf was the length of a city block away from the house, and turned her toward home. Now, of all the things the Lord ever made that can *pull*, it seems to me a young calf is the worst. When they neared the house the calf started to run. Mother was too "game" to let go of the rope, and she came up the hill, taking steps nearly 10 feet long, eyes protruding, hair flying and screaming, "Stop her! stop her!" while the children just laughed until they fell down on the grass. We put the calf in the barn at night, and I remember having hold of the end of the rope when Buttercup started to run. I braced myself and when the rope straightened out the calf shot up in the air and turned a complete somersault, while I went down on my face. After that the children were out every evening to see me take in the calf. We were compelled to sell Buttercup for beef, as she gave so little milk, and never would have made a good cow. Here was another lesson for us in farming. The mother of Buttercup was an extra good cow, but we had spoiled the calf with what we thought was kindness, as many a child is spoiled.

Experience has taught us that skim-milk is better than whole milk for the calf that is to become a cow, and that great care must be taken that the flesh-forming habit is not fastened upon it during its young life. We have found that skim-milk and a gruel made of common wheat middlings *thoroughly cooked* by boiling for 15 minutes will fatten a calf for the butcher without any trouble from scours, and fatten it so well that the butcher would scarcely believe me when I told him it was not a whole-milk calf. An ordinary cow will make a pound of butter a day during its best flow of milk, and in eight weeks it amounts to 56 pounds at 25 cents, $14. As the price of a skim-milk calf is only a cent a pound less, the loss on a 200-pound calf is only $2, showing a gain of $12 to pay for the trouble of butter-making, warming skim-milk for the calf, etc.

G. A. C.

FLABBY FELLOWS
WHO WANT TO BUILD UP THEIR BODIES WILL FIND THE "ONE THING NEEDFUL" IN
DR. PIERCE'S GOLDEN MEDICAL DISCOVERY



The body is built up from the food we eat. But before food can be assimilated by the body it must be prepared for assimilation by the stomach and other organs of digestion and nutrition. *Food does not feed when the stomach is "out of order."* The result is, weak muscles and flabby flesh. "Golden Medical Discovery" heals diseases of the stomach and digestive and nutritive system. It works with Nature to make manly muscle and form firm flesh.

In a letter received from A. D. Weller, Esq., of Pensacola, Escambia Co., Fla. (Box 544), he states: "I have, since receiving your diagnosis of my case, as stomach trouble and liver complaint, taken eight bottles of the 'Golden Medical Discovery' and must say that I am transformed from a walking shadow (as my friends called me) to perfect health."

GALVANIZING A LOAFER FIELD.

One of the most serious problems on our own farm is—what shall be done with the loafer fields? By a "loafer field" we mean one that formerly helped support the family—producing crops that were a credit to the farm—but for some reason has fallen out of service. Nature takes hold of these loafers when man abandons them, and covers them first with weeds, then briers, and finally with trees. When we came to the farm we found at least half of it "loafing" in this way. It was necessary to turn that loaf into a bread-earning capacity, for there was not enough smooth land to produce needed crops. Besides this, we knew well that fields are like men. The longer they loaf the further does nature carry them back toward the point where they are of little value to civilization. We started at once to bring those fields into cultivation. On most of them we tried what we may call the slow-and-sure process. We know it is slow and we *think* it is sure. This consists in roughly plowing the ground in the Spring and sowing cow peas. We prefer to use with the peas a dressing of fertilizer low in nitrogen but high in potash and phosphoric acid. The peas are plowed in, and the following year peas can be sown again, or corn planted with a fair amount of corn fertilizer. This fertilizer will be necessary on such soil to give a fair crop.

Some human loafers are put back into useful work and habits by this slow method, but we probably all know of cases where they have been seized by some sudden ambition or powerful motive, which lent them energy and sent them at once into useful work. Was there any way to galvanize those loafer fields, and make them produce food at once without waiting for the slow process of green manuring? We decided to find out, so we took one field containing about 2½ acres for an experiment. It was a poor light loam—stony and overgrown with brush and briers. It was at the back of the farm, and most old farmers in the neighborhood considered it unfit for cultivation. This field was plowed in May, but instead of sowing cow peas, as was done in the other, we broadcast about 500 pounds per acre of the Mapes corn fertilizer. This was harrowed in with the Acme, the ground marked and planted with Rural Thoroughbred flint corn. This variety does not give a heavy yield of grain, but is the best for silage or fodder that I know. The corn was well cultivated and grew rapidly. By September 1 it stood, in parts of the field, over 12 feet high—the most remarkable tribute to the value of a high-grade corn fertilizer that can well be imagined.

On the north is a field that had not been touched. It was simply a tangled mass of briers, cedars and birch. At the south a neighbor's field was in corn, without fertilizer. This field had been well tilled; but the stalks would barely average shoulder high! At the east is one of the loafer fields which is undergoing the "slow-and-sure" treatment. A few hills of corn planted here were but little over waist high, with mere nubbins in the way of ears. In the midst of these poor surroundings stood the green forest of fertilized corn so thick and tall that a man on horseback riding into it would be lost from sight! We have no platform scales, and could not measure the yield from this field. The stalks, after husking, were run through the St. Albans shredder, giving a roughage which we consider nearly equal to Timothy hay for Winter feeding. We fed no hay at all until March 1, when oat hay was ready. This "loafer field," under the galvanic influence of the corn fertilizer, gave us shredded fodder enough to provide roughage for all our stock for 50 days! Left to itself it would not have fed one rabbit for 10 days. Without the fertilizer it would not produce corn enough to pay for the cultivation. Any farmer who has stock to feed while hay is worth $15 or more per ton, will realize the profit in "galvanizing" a loafer field so that it will leave the haymow free to pay taxes and interest.

This Spring we are following the corn with oats—using more fertilizer. Will this plan of handling abandoned land pay better in the end than the slower way of breeding up the soil with green manures? I cannot answer that until the cow-pea fields have been cropped, but that is not all the story. There are times when we must start *at once* and make such back fields produce a crop from the very start. The soil is in about the condition which doctors term "suspended animation," and galvanic treatment pays in such cases when you *must* have results. I know I obtained such results at a profit. It was the corn fertilizer that induced that loafer field to pull off its coat and walk down to the barn with its load of fodder. H. W. C.

A Practical Dairyman.

About a month ago H. G. M. had an article on weighing the grain ration, and on page 215 someone suggests that probably H. G. M. was a "book farmer," and that he would know more if he got up at four o'clock in the morning to milk, and then carted the milk to the cars or a creamery. I would like to say that H. G. M., with his father, Edward Manchester, and his brother, George E. Manchester, who is secretary of the Connecticut Dairymen's Association, compose a firm of as hustling dairymen as it is easy to find in our State. A year ago last Winter I spent one night at their place. I got there at sundown, one of the coldest nights of the Winter. G. E. M. was in the creamery. The milking of about 40 cows was going on, the "Safe" engine and separator were running. G. E. M. was putting up a special order for brick ice cream. He is the butter maker. H. G. M. and his father have charge of the cows and the feeding and milking, with several helpers, and H. G. M. peddles the skim-milk in the morning. The next morning the mercury was minus eight degrees, and H. G. M. was up before five o'clock, at least, milking. Instead of his usual peddling that morning he was off by train at seven o'clock to speak at an institute in another county. I understand that this firm has increased its herd to about 100 cows since a year ago, and anyone wishing to study a business dairy will be instructed by a trip to Winsted. But the correspondent above referred to should not be entirely condemned for his supposition. We have so many cases of muscular paralysis arising from book education that the business farmer looks askance at the applicant for a job who has been through a college as H. G. M. has. E. C. BIRGE.

Connecticut.

I FEED about a peck of malt sprouts a day to a cow. I feed them dry. A cow will eat them dry after she gets used to them, as well as soaked. I think the reason so many are used is because there is no bad effect from them like corn feed. Most dairymen in this part of the country feed them. I would say 50 carloads are used every year at this station. M. M.

Monroe, N. Y.

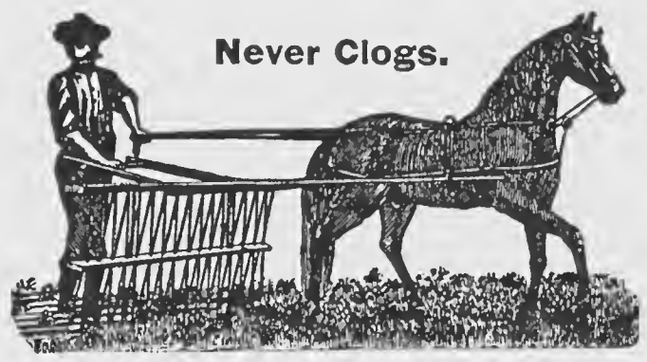
Easy Harness

All harness, old or new, is made pliable and easy—will look better and wear longer—by the use of

Eureka Harness Oil

The finest preservative for leather ever discovered. Saves many times its cost by improved appearance and in the cost of repairs. Sold everywhere in cans—all sizes.

Made by STANDARD OIL CO.



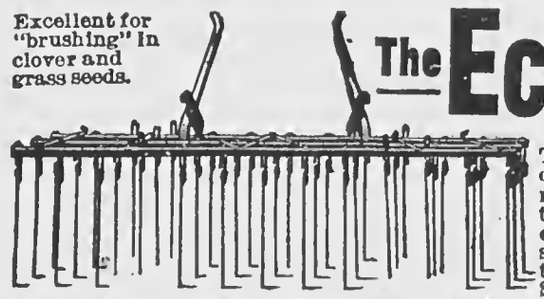
Never Clogs.

BREED'S Universal Weeder

is the best weeder ever made for all conditions of soil. For killing weeds and pulverizing the soil it has no equal. 7 feet 6 inches wide, permanent tooth, and best of material and workmanship. Former price, $8; we will send it direct to farmers for $4 f.o.b., Boston. No agents. You get the benefit. Order at once. The supply is limited.

UNIVERSAL WEEDER CO.,
32 S. Market Street, Boston, Mass.

Excellent for "brushing" in clover and grass seeds.



The Eclipse Weeder

Adopts an Entirely New Principle in Weeders.

The teeth are adjustable so that those coming immediately over the plants in the row may gradually be raised as the plants increase in size. I means that this weeder may be used long after the utility of all other Weeders has ceased. Has 39 oil tempered spring teeth, all adjustable to be raised or lowered, to stand straight, or slant to or from the plants. Stirs, fines and pulverizes all the top soil and kills all weeds, quack grass, etc. Adjustable Shafts—fit any horse. Send at once for *special weeder circulars, &c.*

THE BELCHER & TAYLOR A. T. CO., Box 75, CHICOPEE FALLS, MASS.

It Stands the Storms

better than any wind mill ever invented. This is not only true because of the unusually well constructed and thoroughly trussed and braced angle steel tower, but because of the great strength of the mill itself. It has a way of adapting itself to severe shifting winds.

The Samson Wind Mill

because of its many points of superiority, sprung into popular favor immediately upon its introduction, and is now the recognized leader among machinery of this class. The powerful Double Gear with center line draft, long Interchangeable Boxes, freedom from all torsion and overhanging strain, make it the strongest in the world. Don't buy until you investigate this mill. Samson Art Catalog free.

Sharples "Tubular" FARM Cream Separators

The Wonder of the New Century. Greatest step ever made in advanced Cream Separator construction.

Superior as the Sharples Separators have always been, these Tubular machines are far ahead and completely distance every competitor. They are worth double the money because guaranteed under usual conditions to produce enough more butter than the best competing separator to pay fully six per cent interest on the whole first cost of the machine.

We absolutely warrant it and give free trial to prove it.

Our factory is running double turn, one gang all day and one all night, for the dairyman who sees this machine buys it.

In addition to yielding more butter it is very light running. A 600 lbs per hour Tubular turns as easily as a previous 300 lbs per hour machine No disks to hother with and get out of order, no complications. Washed in two minutes. Top of milk vat waist high.

Highest award—Gold medal and special Knights decoration at Paris Exposition. Valuable book "Business Dairying and catalog No 153, free.

PRIZE CREAMERY BUTTER.

How Milk and Cream Were Handled.

Our milk is received from about 25 small dairies consisting of from two to 35 cows each, and the practice has been to deliver at the creamery only every other day in Winter, while some dairies only deliver once in four or six days. This renders it impossible to make the highest quality of butter, as some of the patrons become a little careless, and the milk is not delivered in the best condition, and often the cream is somewhat frozen. Nearly all the cows from which our milk is received have a little Jersey blood mixed in with a few Holsteins and some native stock. About one-fourth of our patrons are using silos, and all seem to be well pleased with this method of keeping their corn fodder. By the use of silos they are enabled to keep more cows on the same land. As to the quality of milk produced from silage I have no objections to offer provided the silage is good. I can often detect it in the milk when receiving it, but if from good silage it is a flavor which improves rather than injures the butter, as it more nearly approaches green corn or grass, but if from moldy or spoiled silage it is certainly a damage to milk and butter. In making a silo it should be the aim to make it as nearly airtight as possible, even at a little greater cost. Our experience has shown very little advantage in keeping the corn trodden down during filling over the plan of filling slowly and allowing the corn to settle of itself. We find apple pomace makes a very good covering, if put on immediately after filling. Several of the stave silos are being built around here, giving good results.

After the milk is received, weighed and sampled with a milk tube, it is run into the receiving vat together until enough is taken in to keep a United States separator running; then the separator is started and milk taken in as fast as separated. From the receiving vat the milk goes through an Ideal milk heater, where it is warmed to 80 degrees in Summer and 90 degrees in Winter by a jet of steam running directly into the milk. From the heater the milk enters the separator, from which the cream goes into a cream vat and the skim-milk into a vat where the patrons take it, sweet and warm. The cream is held until the next morning, 24 hours, at about 60 degrees, as most of our customers like butter from well-ripened cream. It is churned at about 55 degrees in Summer and 58 to 60 degrees in Winter, well worked in a Fargo worker and packed. We never work but once, as there is no danger of mottled butter if the churn is stopped before the butter is gathered too much, and the wash water is cold enough to prevent further gathering. We salt in the worker, about 1⅛ ounce to the pound, varying somewhat with the conditions of the butter.

Our butter is nearly all sold to local dealers, who order one week ahead, and furnish jars. A noticeable change in the butter trade is the rapidity with which the print butter is increasing. Nearly all retail dealers handle the pound prints now, thus saving all waste and time of cutting out; besides the butter is in much better shape for table use. After the samples of milk are taken at the weigh can from each patron's milk they are placed in a glass bottle and kept for two weeks by the use of bichromate of potash. At the middle and end of each month a Babcock test of this composite sample is made, which gets an average test of all milk delivered, from which each patron's amount of butter is computed, the overrun being given to the patrons, usually from eight to 12 pounds to the 100 or 108 to 112 pounds of butter from 100 pounds of butter fat, as butter only contains about 85 per cent butter fat. W. G. COMSTOCK.

Chuckery, N. Y.

Milk Notes.

DURING the recent "milk war" in Boston the New York dealers shipped a good many carloads of milk to help out the Boston dealers.

THE question is up as to whether a milk producer should pay himself a salary. It won't take the milk dealers long to answer that question.

WE are selling our milk to a New York dealer at Exchange price less one-half cent per quart, and are dissatisfied with the price, which seems to be about the situation here at present. W.

Valley, N. J.

THE milk producers seem to be powerless to fix and maintain a living price for their product in New York and other cities. We are simply being skinned alive by these New York dealers, who are growing rich at our expense. G. B. M.

I AM glad you are after the "Polar Creamery" sharks. They were all around here in December; they did not do very much in this neighborhood. I think they sold two within five miles of here. They claimed they had sold over 200 in Clearfield County, and about 40 in Jefferson County, when they were here. Their mode of business was very similar to that of a certain steel range company who canvassed this section in 1892 and 1899-00; their prices, agreements, warrantees, are almost identical. J. G. W.

Pennsylvania.

LAST October the Scranton Dairy Company commenced to buy milk at Fosters, Pa., and agreed to pay $1.15 per can until April 1, 1901. They took the milk, from upwards of 80 producers, until December 8, and then notified the patrons that they would not take it longer, except at butter prices. Most of the patrons withdrew and test suits were instituted against the company, and they agreed to settle and pay for the milk through December at full price as agreed upon, but did not, as they found the farmers were afraid they would lose their money, so they made them an offer of 70 per cent, which most of them took. Others who held off awhile got more, some of them 90 per cent, but two farmers of Brooklyn and eight farmers of Dimock brought suits against them, and have just recovered full pay with interest and costs, and damage enough to more than pay their attorney. F. H. B.

ABOUT the middle of December the milk producers of this section formed a stock company with a capital of $10,000 to go into the manufacture of soft cheese and butter. We opened our factory April 1 and are getting about 7,000 pounds of milk daily. We expect about 2,000 more in the flush. Our building is 92x98 feet and two stories including cellar. It is equipped with 35 horse power boiler, 12 horse power engine separator, four large cheese vats, twin cream vat, Simplex combined churn and worker, De Laval separator. The officers of our company are: D. W. Matteson, president; L. E. Carpenter, secretary and manager; W. S. White, treasurer. The foreman of the factory is Wm. Bilyou, an expert Neufchatel maker. Henry Eiderman has charge of the Brie department. We employ nine hands at present. Our goods are handled by A. L. Reynolds.

So. Edmeston, N. Y. W. S. W.

I AM well pleased with the show-up of my fodder-roofed shed in THE R. N.-Y., page 205. I commenced feeding the roof off three days ago. There is but little of the fodder damaged. Next week I expect to sow 11 acres to Spring barley and Alfalfa. A good many are making a start that way. March 29 I sold 90 lambs in Cincinnati at six cents per pound; the remainder, 18, $5.50 per 100. This is much better than I could have done by shipping to eastern markets. JOHN M. JAMISON.

It Will Cost You Nothing

to skim all your milk for ten days with the

NATIONAL Hand Separator

You may have one absolutely without cost (you'll be under no obligation to buy) to thoroughly test for ten days. Return it if you're not satisfied that it's the most profitable machine to buy. Write now.

National Dairy Machine Co., Newark, N. J.

BIG USERS OF CREAM SEPARATORS

The Continental Creamery Co., Topeka, Kan., uses 175 De Laval Power Separators. The Elgin Creamery Co., Chicago, uses 150. The Borden Condensed Milk Co. uses about that many. The Beatrice Creamery Co., Lincoln, Neb., uses 135.

The Franklin Co. Creamery Association, St. Albans, Vt., uses nearly 100. So does the Standard Butter Co., Owego, N.Y.

The Brady-Meriden Creamery Co., Kansas City; Parker Creamery Co., Hutchinson, Kan; and John Newman Co., Elgin, Ill., all use over fifty machines each.

The St. Mary's Creamery Co., St. Mary's, Ont.; Fairmont Creamery Co., Fairmont, Neb.; McCanna & Fraser Co., Burlington, Wis.; Belle Springs Creamery Co., Abilene, Kan.; Forest Park Creamery Co., Edgerton, Kan., and the Hesston Creamery Co., Newton, Kan.; all use from 25 to 50 machines.

All these are large Power machines, costing $500 to $800 each. In addition, some of these concerns have hundreds of "Baby" De Laval machines scattered among their patrons.

Every concern named, as well as every other large user of separators, now uses and purchases De Laval machines exclusively.

THE DE LAVAL SEPARATOR CO.

HAVE YOU SEEN

The New Bowl?

That's the question you now hear wherever cream separators are used. It refers to the light and easy-running bowl now used on the

EMPIRE Cream Separator

—the bowl with few parts, and perfectly smooth surfaces—the bowl which gives the milk several distinct separations.

Our new catalogue for 1901 shows why the EMPIRE is the most practical, the easiest-running, the most efficient for the farm. May we not send you a copy?

United States Butter Extractor Co., BLOOMFIELD, N. J.

Quaker Dairy Feed

TESTIMONY

BENSON, Md., March 21, 1900.

GENTLEMEN:—

I have been feeding Quaker Dairy Feed to my herd of cows since the first of last December and have had most excellent results from it.

I have fed it mixed with mill feed and cob meal, also unmixed. I can readily notice the increased flow and quality of milk in each instance, but I think the best results I have obtained is when I used it with my rough feed. I expect to continue feeding Quaker Dairy Feed during the coming summer, and I cheerfully recommend it to dairymen as a profitable feed to use. Very respectfully,

JOSEPH B. HOSKINS.

OUR GUARANTEE.

Sold only in Sealed and Branded Sacks. Each Sack stamped with analysis of contents, showing guaranteed per cent. of Protein.

If your dealer does not keep Quaker Dairy Feed send his name to us and get a free copy of 'Modern Dairy Feeding."

CHEESE CHEESE BUTTER BUTTER CHEESE CHEESE

Ailing Animals.

ANSWERS BY DR. F. L. KILBORNE.

Wart on Cow.

I have a cow that has a wart growing on one of her teats. The roots grow into the end of teat and stop the flow of milk. I have tried almost everything. What would you advise me to do for it? The wart has been on about a week. A. W.
Ludlowville, N. Y.

Apply night and morning, after milking, a lotion of carbolic acid one part, and castor oil three parts, well shaken up together.

Horse Out of Condition.

I have a mare 11 years old; she has been out of condition since last November with some kidney or bladder disease. Her coat is smooth but her body is thin; eyes dull; has not much life in her; seems to be stiff through the body and down the hind legs; is not weak in the back; passes urine often but little at a time. Has not a very good appetite; lies down during the night as usual; goes on the road as if tired. I do not work her much at present. I have been feeding various kinds of condition powders, but all failed. I feed her three quarts of wheat bran and corn and oats daily, and all the upland hay she will eat. Is there any medicine that will cure her?
Libertyville, Ill. A. S.

Give one of the following powders in feed twice daily: Powdered nux vomica and nitrate of potash, of each four ounces; gentian and ginger, of each eight ounces; mix and divide into 24 powders.

Horses Fail to Shed Coat.

My horses do not shed their hair well every Spring. One is a gelding, nine years old; he does not digest well, but is in good flesh and stands work. Another is a mare with foal; she has a spot that is a little scabby on udder and neck She is eight years old. The third is a colt that will be one year old in May that looks rough and drowsy; it seems to have worms. The last is a mare; she is otherwise all right except in shedding. I feed corn for grain and corn fodder and cut sheaf oats. Give cause and treatment. READER.

Give one of following powders in feed once daily (the colt should receive only one-fourth of a powder): Arsenic, two drams; powdered nux vomica, four ounces; gentian, 16 ounces; mix and divide into 40 powders. The animals should receive a thorough grooming daily. Replace one-half of your corn with oats or bran, or a mixture of both. A handful of oil meal added to the grain ration twice daily will materially improve the appearance of the coat.

Indigestion in Cows.

Several of my cows, one after another, lose their appetites; eat hay well, but not silage or grain, especially grain. Feed three quarts twice per day when they will eat it; gluten, oat feed, bran, corn meal and linseed. Feed seems to do them no good; they grow poor and shrink in milk. They grate their teeth frequently; sometimes are troubled with a good deal of gas. Voidings for the most part are natural. Bright and active, but coats rough. They have roomy, light, sunny and well-ventilated stable. Some of them when turned out eat dry leaves and such rubbish. What is the trouble, and what the remedy? Are cows ever afflicted with stomach and intestinal worms? If so, what is the remedy?
Holden, Mass. H. A. R.

The cows are suffering from indigestion. There would appear to be some fault in the care or feeding of the cows, possibly in the feed itself, but what I am unable to say from your description. Call in a competent veterinarian personally to examine the herd, and the conditions under which they are being fed and cared for.

SILAGE AGAINST STONE WALL.

B. W., on page 213, asks what to do about silo with a stone wall at the bottom. Prof. Clinton thinks that possibly air gains entrance at the junction between wood and stone. This is probably the source of the trouble, rather than the stone wall itself. In our silo at my old home we had a clay bottom, a clay wall plastered with cement on one side for about seven feet in height, stone walls on two sides 10 feet high, and the remainder of the 25 feet was two thicknesses of lumber with tarred paper between. The joint between the stone wall and the wood was made as shown in Fig. 120. A represents the stone wall, B double plank for sills, C studding, D and F the two courses of boards, with the tar paper, E between them. G represents patent dovetailed lathing, which is simply good stock boards with dovetailed grooves to hold the clinches of the plaster. This lathing was put on in place of the inside boards for about 1½ foot above the wall, and lapped over the joint between stone wall and sills—a jog being left in the stone wall for the purpose, as shown in Fig. 120. Then the inside of the wall was plastered with a coat of cement, which was run up as high as the patent lathing, as shown. This made a perfect joint, and we never could see any difference between the silage which was against the wood or

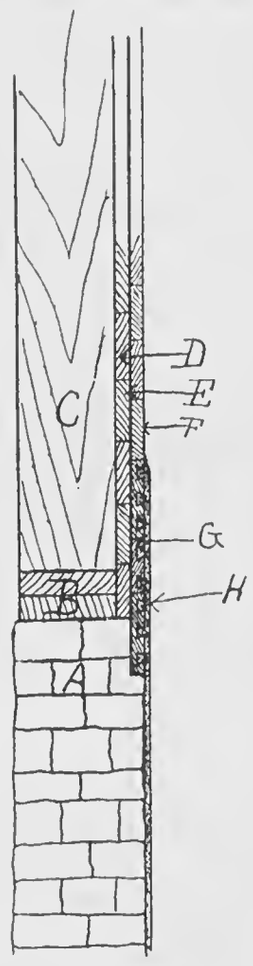

Fig. 120.

stone or clay. About two feet of silage was once left in the silo three years, and was in perfect condition against the clay bottom. J. M. DREW.

MILK.

William Schmidt	$50 and costs
Reuber Satenstein	50 and costs

SOILING AND PASTURING.—An acre of ground is in grass or some cultivated forage crop. You cut this green fodder, carry it to the stock and let them eat it. That is soiling. You turn the stock into the field and let them eat the crop at will—that is pasturing. Which is more profitable? The Nebraska Experiment Station, after testing it carefully, says: "A comparison of the relative amounts of feed produced by several forage crops when pastured and when soiled indicated that the latter practice secures two to three times as much feed from the same area of land The same tests indicated that the average daily production of milk and butter fat was greater for the same feed when the cow was pastured than when soiled. This on an average amounted to 1.17 times greater butter-fat production from the pastured than from the soiled crop."

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee

South Dakota Adds Another Stone to the United States Triumphal Arch

A separator contest was held at Oneota Hall, Aberdeen, S. D., March 18, 1901, to determine the comparative merits of the United States, Sharples and DeLaval Separators. Mr. A. W. Burnham, a prominent and well-known citizen, was appointed by the farmers and separator men present to act as "Dairy Expert" and take charge of the contest and give official results of the same. As will be seen by the report given below,

The Improved United States Separator

Again Proved its Superiority over all others and

Was Awarded First Place

Make of Separator	Selling Price	Rated Capacity	Capacity During Test
United States No. 6,	$100.00	350-400	408
Alpha Baby No. 2,	125.00	450	448
Sharples Tubular No. 6	175.00	650	628

THE U. S. AHEAD.

A. W. BURNHAM, Dairy Expert.

WITNESSES { S. A. STEARNS, J. M. HURST, D. G. VAUGHAN, JOHN GAULY, C. N. GAMBLE, F. H. LEACH. GEO. W. MANTOR, C. A. MCARTHUR,

The United States run over its highest advertised capacity and skimmed the cleanest while the others run under their advertised capacity.

Notice how much larger capacity the U. S. gives for the money, in addition to its cleaner skimming, than the others. To have equalled the United States it would have been necessary for

The DeLaval to have skimmed at the rate of 610 lbs. instead of 448 lbs.
The Sharples " " " " " " " 714 " " " 650 "

All of which goes to prove the correctness of our claim that when utility and price are considered the

When you buy a carriage, buggy or harness. Choose from the biggest stock and fullest assortment, and pay only the cost of making, with but one moderate profit added. Our plan of selling direct from the factory insures satisfaction—your money back if you're dissatisfied with your purchase—and enables you to **save the dealer's profit.**

Our complete illustrated catalogue, showing many styles of high grade vehicles, harness, robes, blankets and horse equipments, with detailed descriptions of each, mailed free. Write for it and learn how cheaply you can buy when the jobber's and dealer's profits are cut off.

THE COLUMBUS CARRIAGE AND HARNESS CO., Box 772, Columbus, O.

No. 240. Single Strap Buggy Harness. Price $7.95.

QUALITY

Carriages and buggies which are right all the way through. That describes the famous

Split Hickory Vehicles

In material and construction they are as good as American skill and enterprise can produce. They have a dozen little things about them which add to their durability, safety, comfort and appearance. Don't buy a vehicle before you have investigated the SPLIT HICKORY line.

Ohio Carriage Manfg. Co.,

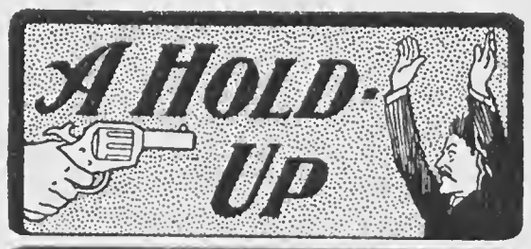
PRICE

We sell direct from the factory and save you all of the dealers' and jobbers' profits, and WE SHIP

On Approval to Anybody.

If you are not perfectly satisfied return the vehicle at our expense. Send for our illustrated book of Vehicle and Harness Bargains. It contains many things concerning vehicle values, which you ought to know, whether you buy of us or not. It will save you dollars.

39 W. Broad St., Columbus, O.



Is not always the work of a highwayman.

When a dealer charges you from 35 to 50 per cent more for a carriage or harness than we would charge you direct for the same, or better, you are certainly being held up. This however, is not the dealers fault. He must live, but why at your expense? We sell our vehicles at factory prices and save you both the jobber's and dealer's profit. We do still better; we send our vehicles on **10 Days Free Trial.** Try it before you buy. If not wholly satisfactory return it at our expense. Write to-day for our free illustrated catalogue.

Kalamazoo Carriage & Harness Co.,
Box 30, Kalamazoo, Mich.

STUDEBAKER QUALITY

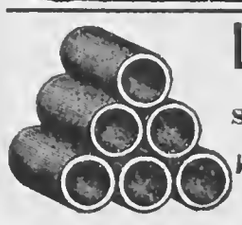
Do You Use THE STUDEBAKER?

If so, cut this out, and enclose it with your letter, stating from whom you purchased the wagon, date of purchase, and its condition to-day, and we will send you free of charge

The Studebaker Almanac,
The Studebaker Grand March,
The Studebaker Twentieth Century

circular which tells you all about this great wagon.

STUDEBAKER BROS. MFG. CO., South Bend, Ind., U. S. A.



LAND DRAIN TILE

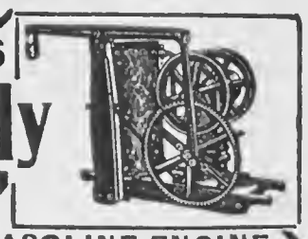
(Car-loads or less).
Sizes, 2, 2½, 3-inch and up to 15-inch.

WILLIAM T. LEGGETT & CO.
1025 Liberty Avenue, Pittsburgh, Pa.

SILOS

HOW TO BUILD ASK WILLIAMS MFG. CO., KALAMAZOO, MICH.

WEBSTER'S "Handy Man" GASOLINE ENGINE



with walking beam Pump Jack and gasoline supply tank, all on one base. It is the handiest, most complete, economical and efficient small power made. Engine 1½ actual h. p. By disconnecting pump jack and putting belt on fly wheel pulley it is ready for **grinding, shelling, cutting feed, separating cream, churning, cutting green bone**—anything not requiring more than 1½ h. p. Costs little for fuel and requires no experience to operate. We also make other sizes of vertical and horizontal engines for all purposes. Send for large catalogue.

Webster Mfg. Co., 1091 West 15th St., Chicago, Ill.

The Rural New-Yorker

THE BUSINESS FARMER'S PAPER.

A National Weekly Journal for Country and Suburban Homes.

Established 1850.

HERBERT W. COLLINGWOOD, Editor.
DR. WALTER VAN FLEET, H. E. VAN DEMAN, MRS. E. T. ROYLE, } Associates.
JOHN J. DILLON, Business Manager.

SUBSCRIPTION: ONE DOLLAR A YEAR.

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs.

"A SQUARE DEAL."

We believe that every advertisement in this paper is backed by a responsible person. But to make doubly sure we will make good any loss to paid subscribers sustained by trusting any deliberate swindler advertising in our columns, and any such swindler will be publicly exposed. We protect subscribers against rogues, but we do not guarantee to adjust trifling differences between subscribers and honest, responsible advertisers. Neither will we be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent us within one month of the time of the transaction, and you must have mentioned THE RURAL NEW-YORKER when writing the advertiser.

Name and address of sender, and what the remittance is for, should appear in every letter.
Remittances may be made in money order, express order, personal check or bank draft.
THE RURAL NEW-YORKER,
409 Pearl Street, New York.

SATURDAY, APRIL 20, 1901.

ON page 297 we print the names and addresses of 20 rogues who have been found guilty of selling oleo or watered milk in this city. They have been well punished and we are glad to hold them up in black ink for the scorn of their fellow-men. One name, "Satenstein," is peculiarly appropriate for a man who would engage in such a business. That is not a bad name to give some of the big rogues in Congress who do more damage by their voting and wire-pulling than these little men do by selling!

*

As will be noted on page 290, we begin this week a new department of Nature Study edited by Prof. John Craig, of Cornell. THE R. N.-Y. has always regarded this method of teaching the principles of soil culture as being a connecting link between the college and experiment station and the common people. We take pleasure in introducing Prof. Craig and his 40,000 pupils, to the readers of THE R. N.-Y. As usual we make no claims or promises for the new department beyond the statement that we believe it will contain the cream of the enormous correspondence which this popular course is bringing out.

*

SECRETARY Wilson, of the Department of Agriculture, intends to put in operation next year a new plan, being the distribution of young trees throughout the country. The distribution will be made in a manner somewhat similar to that employed in the free seed distribution authorized by Congress. Especial attention will be given to the nut-bearing trees, and to those suitable for shade, efforts being made to select those specially suited to different localities. Secretary Wilson believes that the plan will prove very popular, and that it will be of decided benefit to the country. The diminishing forest reserves suggest that we need encouragement in tree planting.

*

A MAN owns an ornamental hedge so covered with San José scale that it is a menace to an entire neighborhood. His next-door neighbor is desirous of planting trees and shrubs extensively but he is afraid to do so, because this would only invite further spread of the scale. Moral suasion has no effect on the owner of the hedge, who refuses to destroy it, and though a State law orders the destruction of such infested plants, there is some doubt whether such a law is constitutional, nor is there money to enforce it. The result is that a would-be planter looks sadly at barren lawn, which he would gladly plant with handsome shrubs, and some nurseryman loses the chance of a good order, while one selfish owner views complacently a slowly-dying hedge, which is industriously infesting its plant neighbors. What can they do about it?

*

THERE are many people still who know very little about the work done by the American experiment stations. Some interesting figures are given by A. C. True in a recent bulletin from the National Department of Agriculture. There are 54 of these stations, with 693 workers. The total income from all sources last year was $1,170,857.78, and it was practically all spent. The National Government provided $719,999.07, and the various States $247,281.46 more. From the farms connected with these stations $90,088.84 worth of farm products were sold. During the year 386 bulletins and reports, covering 14,172 pages, were issued. There are 562,851 names on the combined mailing lists of the 54 stations. These figures give but a faint idea of the vast and elaborate system of scientific investigation that has been organized in the past 15 years. The time has come when every farmer who takes pride in his profession should acquaint himself with the station work. It is surprising that with the millions of people depending directly upon the soil for their support, such a comparatively small number should receive the station publications. The highest single list is 36,000 names for the Geneva (N. Y.) Station, while more than half the number have less than 10,000. What can be done to bring the help which the station offers closer to the farmer who needs it most?

*

HERE is a case similar to that of the man who fell overboard with a bag of money, which, as he refused to drop it, dragged him under before help could reach him. A liquor dealer in Brooklyn, N. Y., was lifting on a barrel of whisky, when the chine happened to press on a large diamond ring he was wearing, in such a way that the ring cut his finger severely. He died from the effects of the wound, as blood poisoning set in. Of course such an accident might have happened to a grocer in handling a barrel of sugar, but as a rule grocers do not wear diamonds and are not so thoroughly pickled with liquor that slight wounds refuse to heal. There are saloonkeepers who never touch the stuff themselves, but they are exceptions.

*

WE are asked whether the export trade in ginseng root is likely to be kept up by foreign demand. Thousands of people, apparently, are planting seeds or roots of this plant. Our opinion is that the great majority of them do not realize the care required in growing this crop, and that they will fail; still, the output is quite sure to be increased. What about the future demand? Most of our crop is sold in China. As we understand it, the root has but slight medicinal value. The Chinese demand is based largely on superstition. As the Chinese Empire is opened or carved up by the swords of modern civilizers we think this superstition will die out, and that modern ideas of medical practice will prevail. Judging from past experience, increased exports of whisky and beer are more likely to "follow the flag" than any larger trade in ginseng.

*

THE steel industry of this country has just been organized with a capital stock of more than a billion of dollars. This "infant industry" now is under the direct control of one man. He is protected by a liberal tariff, from foreign competition. At home he has no rivals or competitors. Every individual who uses a pound of steel will pay tribute to him. This will apply to the United States Government, which is a customer for material for battleships, as well as to the farmer who purchases a plow, a reel of wire fencing, or even a pound of nails. When first announced the country was startled with the magnitude of this combination of capital, and the individual control of so large and important an industry. But there is already under way another project that will compare with the steel combine in proportion as a camel would to a gnat. This is no less than the consolidation of all the main lines of railroads in the country under one corporation. These enormous combinations of capital all lead to one final result—government control and government ownership of public utilities.

*

IN the latest issue of the Review of Reviews K. L. Butterfield describes what he names "the Hesperia Movement." Hesperia is a town in western Michigan—a small village a dozen miles from a railroad. It is surrounded by good farms, and the Grange is strong thereabouts. It happened that about 15 years ago the teachers in the rural schools about Hesperia were a very bright and original group of young men and women. They formed an association of their own, and concluded to ask the farmers to meet with them. This idea was carried out, and the meetings became popular, for both teacher and parent were represented on the programmes. The result was a permanent association which has held regular meetings and achieved results of great practical value. As many old teachers well know, the parents in many rural districts take little personal interest in the school. The tax-payers often growl and the parents find fault, yet the teacher is unable to coöperate with them as he would gladly do. The object of this "Hesperia Movement" was to bring tax-payer and home-maker into an association with the teacher, and this seems to have been a great success. There are better schoolhouses, better school yards, better fixtures and better teachers. Better books are read and there is a higher standard of citizenship. Life is better worth the living, for the people have higher and nobler ideals. This movement has spread into several counties of Michigan—always with good results. The Grange has proved helpful—in fact, without its aid this movement would probably have failed, since the Grange had tilled and fertilized the soil in which the seed was planted. This movement is commended to other localities. It is always desirable to bring pupil, parent and teacher closer together.

*

WE probably have more questions from would-be farmers—city men who wish to try country living—than any other paper in the country. It would be very easy to set such men wrong. They are eager, and look upon farming as an easy job. The grass and the trees grow easily, they reason, and therefore it must be easy to steer nature into profit. The advice we give may be estimated by the following note from one of our readers:

> Three years ago I asked your advice in regard to the purchase of a small farm as a future home in declining years. Your advice was to go slow, "as the pay days are wide apart and sometimes do not come at all." All you said I have found correct. In three years the pay day has not come; corn, wheat and potatoes have not paid. I now want to try grass.

This man, like many others, must learn that years are required to master the business of farming. A long lifetime finds most men so far short of mastery that untimely frost or drought may upset their best plans. The man who plants an apple tree knows that he must work 10 years before he can hope for a good crop. We do not realize that we must also work more than 10 years with strawberries or potatoes, or cabbage, or grass, before we can master the foundation principles, and really understand the crop. Too many of us raise three crops and then stop studying—thinking that we know it all!

*

BREVITIES.

Here are some certain rules of health;
Take them—they're better far than wealth,
Don't overeat, don't overdrink,
Don't overwork, don't overthink.
Be not afraid of honest sweat;
Run like a deer from shame and debt.
Let not your right hand ever know
What gifts through your left hand may flow.
Beware of bigness of the head;
Get bigness of the soul instead.
Shun whisky as you would a curse,
And no tobacco funds disburse.
Love and respect your fellow man,
Or come as near it as you can.
Eat two good apples every day
And take two solid hours for play;
And keep this thought in mind, my friend,
That when your busy life shall end,
The prize will not be held by one
Who what men brand "success" has won,
But by some humbler one who yet
Leaves to the world least to regret.

WE are what life makes us.

SUGAR plums never cured one of a bad habit.

WE like to see a man's character "sparkling with do."

WHO ever learned a real lesson except through suffering?

"DO men gather grapes from thorns?" Yes, sour grapes.

PEOPLE of the Russian steppes show a desire to make the Czar walk Spanish.

THE strength of the will power is determined by the ability to say "I won't."

SOME folks make their bed and then instead of lying in it try to lie out of it.

GRIND the family skeleton into bone meal and use it to fertilize true repentance.

THE best work most of us do is squeezed out of us by the pressure of hard conditions.

A MAN in this city who has lost his left arm and the left leg is nick-named "all right."

THE ability to live on the farm—you can make it a glorious privilege or slavery—as you will.

RAISE fruit that suits some well-heeled fellow's fancy, if you would pocket price and profit prancy.

THE keystone of American citizenship is the hearthstone. Too many town dwellers never know what this is.

ONE man objects to THE R. N.-Y. because "there are so many good things in it that it causes me to burn up good oil."

MANY maple trees in New York State are reported so damaged by storm or forest worm that they will not be tapped at all.

"THE evil that men do lives after them." One reason for this is the fact that most of us publish the evil about others and lock up the good.

MR. CORBETT, on page 293, backs up the recent article by Prof. Roberts in a striking way. It is wonderful how the scales, test and pencil will show up the robber cows.

ENGLISH farmers are demanding seed testing stations. It seems that English farmers can obtain good seeds if they are willing to pay enough for them, yet a vast amount of worthless stuff is sold.

IT is said that the oldest English advertisement is a "lost, strayed or stolen" notice inserted by King Charles II. for a little dog he had lost. We are not told whether this advertisement paid.

POMELO is the proper name for what the market calls "grape fruit;" but what would you get if you called for it properly in the average fruit store? It would be like asking an Italian peanut man for a pint of legumes.

NEW YORK STATE FRUIT PROSPECTS.

Early Outlook is Favorable.

The New York State Fruit Growers' Association has begun active work. Branch societies have been formed in several counties. Wayne County fruit growers met last week at Newark and organized successfully. Niagara, Oswego, Orleans, Ontario and other counties are moving. One object of the Society is to gather reliable statistics. We give herewith the first report of the new parent Society. The following brief statements are typical. In general the reports are favorable. Peaches do not promise a heavy crop. Apples are well budded, but indications are that insects will be numerous and deadly. Small fruits are fair in some sections—poor in others. The Hudson River Valley reports a poor outlook for strawberries. Bush fruits have suffered from drought and disease. The Winter has, on the whole, been favorable to fruit, yet it is altogether too early to make definite statements. On April 1 about all salable apples were out of farmers' hands, with probably 40,000 barrels left in cold storage in Orleans and Niagara counties. The interest in spraying is growing. Next week we shall give a report on this part of the business. Reports from the country at large show that fruit buds generally look well, especially in the large orchard States. As a rule, small fruits, especially strawberries, are not promising.

The first of the northern Florida strawberries reached New York, April 11. It will be at least two weeks before any of the Charleston crop come in, the usual time being May 1. Ten days or two weeks after this the line of ripening will strike the North Carolina fields, where it is said that the drought of last season injured the stand of plants.

Speaking of the work Wayne County is doing, L. T. Yeomens, president of the Fruit Growers, says:

"I am proud of old Wayne; she has nearly 50 members of the New York State Fruit Growers' Association, and more to come. Wayne County had an old Fruit Growers' Association, dead for past year or two. We revived that as a starting point."

I have examined buds on peach and pear trees, and have found them all in good condition, and the prospects are for a good crop of blossoms at least. A. C. P.
Oswego Co.

Fruit is coming through in fair shape. Our old peach trees broke badly in Winter by ice; fruit in general damaged from the same cause. E. F. F.
Ontario Co.

Peaches, plums, and in fact all small fruits have wintered well, and the prospect is good for a fine crop. From present indications there will be a fair blossom of apples and all trees in fine condition. S. W. W.
Monroe Co.

Small fruits came through the Winter in fine condition; trees of all kinds are looking well. As far as I have noticed most of the apple trees bid fair to give a moderate bloom. A. D. C.
Wayne Co.

Small fruit has wintered in this district of Seneca very well; the lowest temperature at my place was three degrees above zero. Fruit trees appear to be all right. In my orchard the trees are mostly Baldwins and Greenings.
Seneca Co. J. W. S.

The small fruit seems to have come through the Winter well, but does not seem to be as full of fruit buds as last year; in fact, all trees are not as full of fruit buds as last season, except those that did not bear. E. A. C.
Niagara Co.

The May frosts we fear for our grapes. By covering, the most tender varieties winter well. Plums bore a heavy crop last year, but show some buds now, most of which came through the Winter all right. Apples are going to bloom somewhat; pears also. D. W.
Onondaga Co.

Small fruit came through the Winter well, with the promise of a fair blossoming. Pears, peaches, plums and cherries will blossom for a medium crop of fruit. The prospect for apples is not as good; the promise for a Baldwin crop is very small in this part of the county.
Monroe Co. C. S. W.

Small fruit has wintered in good condition, and the outlook was never better for trees, especially where sprayed; and about 25 per cent of the fruit growers spray, which embodies about 50 per cent of the trees, and about 25 per cent of the trees, we think, are sprayed successfully. J. G. W.
Albany Co.

Small fruit came through the Winter well. The temperature went but few degrees below zero at any time during the Winter, and the climatic conditions have been such that fruit buds at the beginning of April showed no development, which fact insures them to a large extent against the danger of a late frost. A. H. MCM.
Wayne Co.

Strawberries will be a light crop. Blackberries are badly winterkilled, or by drought last Summer. Raspberry prospects good; currants, average crop. A great deal of cane blight last season. Peaches, young trees, look well, old trees are in bad shape from dry season last year; sour cherries seem to be all right; pear buds look well. J. A. H.
Ulster Co.

Small fruits have gone through the Winter in good shape and show a fair average of blossom buds. The Greening apples show prospect of full amount of blossom buds, while the Baldwin shows a light one, also Spy and Roxbury Russet. Taking it all in all present indications go to show a fair average all-around fruit crop, whatever may happen later on. C. W. O.
Niagara Co.

Strawberries, where not mulched with straw, are not in good condition. The plants, owing to the extreme drought of last Summer and Fall, rooted very shallow, and where not covered have heaved out badly. Owing to scarcity of straw most beds were left uncovered. Raspberries, red and black, are all right, and promise a good crop. Peaches and plums have not been injured by cold, but it is doubtful whether there is vitality enough in the buds to set fruit, owing to the long-continued drought, although freedom from fungus trouble last year may help them out. G. H.
Onondaga Co.

There is not a very large show of fruit buds on the apple trees; peaches are full of them and all trees came through the Winter in fine condition. Pears are not grown to any extent here. All of the berries made small growth last Summer, and the heavy snow broke the canes down considerably. Raspberrics blighted badly last Summer, many shoots of some varieties dying. Peaches are probably the only fruit in this section that can make a full crop. J. Q. U.
Ontario Co.

Fruits are apparently in satisfactory condition. On a few low fields not well drained strawberries suffered from freezing nights, but there is little of that kind of land hereabouts. Raspberries of all sorts have wintered finely. The fruit tree buds are 100 per cent good, so far as my investigation goes, with slight exceptions in apricots. Best of all, I find no eggs of the tent-caterpillar, but occasionally a cluster of shells from which the eggs appear to have been taken. J. T. R.
Onondaga Co.

We have had an idcal Winter for the fruit business, with no low temperature to kill even so much as a bud on the peach trees. Strawberries that were set early last Spring, and well cared for and mulched last Fall, give promise of a good crop; otherwise not, for we had a severe drought last Summer. Where other small fruits were not allowed to overdo last year the outlook for a crop is first class. Where apples and pears were well cared for with cultivation and spraying, and not allowed to overbear, they seem well loaded with fruit buds.
Oswego Co. C. B. C.

Orchards are in good condition. Greenings are very full; Spy, King and some other varieties are well budded. Baldwins overbore last season, and many of the trees have no fruit buds. I think the above will apply to this section, except perhaps some King and Spy which bore heavily last season will fail. Our peach trees, consisting of Elberta, Crosby and Wager, are well budded. Crosby and Wager were very full last season. As nearly all peach orchards about here were either cropped or received no cultivation last season, and were overloaded, I do not think many of them will bear. Plums and pears are well budded. C. R. W.
Ontario Co.

POSTAL CARDS.

CERTAIN farmers in California grow what is called the pie melon for stock food. It is said to be a cross between watermelon and citron with a vine much like the former. Cows and hogs are both very fond of it.

A READER wishes to know whether it will do to sow Alfalfa on wheat or rye the same as is the custom with Red clover. No, Alfalfa does not wish to play second fiddle to any crop, and must be seeded on fresh ground, which it thoroughly monopolizes.

IT is safer to buy wood ashes or hen manure by weight than by the barrel. First-class, unleached wood ashes are worth $8 or $9 per ton, and average hen manure $6 or $7, varying according to the way it has been kept and the amount of feathers and dirt contained in it.

IT often happens that on light soils the best fertilizers will not produce a good crop in a dry season. This may not be the fault of the fertilizer, but because of lack of humus in the soil. This vegetable matter holds water like a sponge, giving it out to the roots of the plants as needed.

NO, we would not advise anyone to plant a field of artichokes unless he wishes it to remain in artichokes all the rest of his life. This plant will take a rod for every inch given, and hold on with a death grip. The best place for artichokes is a hog yard. They make fair hog food, and, if the hogs are not rung, they will enjoy rooting out the tubers.

AMMONIA and nitrogen are not identical, as some fertilizer makers attempt to make farmers believe. Nitrogen is a single element, while ammonia is a mixture of hydrogen and nitrogen. Every pound of ammonia contains about one-fifth hydrogen, which has no value as a fertilizer. Also, sulphate of potash contains only half its weight of actual potash, the remainder being a worthless form of sulphur.

NO, Crimson clover should not be sown in Spring. It is a cool-weather crop. The heat of Summer will make it head out and go to seed when only three or four inches high. Any time after July 1 it may be sown safely with a fair chance for success. Then it will make its growth in the cool weather of Fall. It is a good plan to sow it in the cornfield at the last cultivation. It will thus furnish a cover crop for the field during the Winter.

ABOUT the only plant food in coal ashes is a small quantity of lime. The prehistoric plants which by their decay through thousands of years have formed the beds of coal we are now mining, apparently contained but little potash or phosphoric acid, and what there was leached out as the coal was formed. The chief value of coal ashes is in their mechanical action. When mixed with some light sandy soils they help them to retain water. Also, they are useful as a mulch for currant bushes or pear trees. They pack down close to the ground, and help retain moisture in time of drought.

A FERTILIZER for long-growing crops should contain plant food in a variety of forms so far as solubility is concerned, so that it may become gradually available during the season. Otherwise in justice to the crop several applications would be necessary. Nitrate of soda is the most soluble form of nitrogen, and becomes immediately available to the young plant, no matter how cold or backward the season. By the time this is exhausted, the sulphate of ammonia has become soluble, feeding the plant through May and early June. Next come the organic forms, such as blood, tankage and cotton-seed meal, which require heat and chemical changes in the soil before becoming suitable plant food, and, in the case of potatoes or corn, take care of the plant until the tubers or grain are formed.

Events of the Week.

DOMESTIC.—A terrific windstorm swept over Charleston, S. C., April 2, doing much property damage. . . . . In northern Kansas, two feet of snow fell April 2; many cattle died on the ranges, and a food and fuel famine followed. . . . . April 3, there was a heavy snowfall in Pennsylvania, Maryland and West Virginia. . . . . April 6, a trolley car broke through a bridge at Syracuse, N. Y., precipitating 40 persons into the bed of the Oswego Canal, 30 feet below. The canal was dry; 30 persons injured. . . . . A fire at Lisbon Falls, Me., April 6, destroyed 28 buildings in the business section of the town; loss, $250,000. . . . . Boer representatives at New Orleans have brought injunction proceedings against the shipment of mules to the British army in South Africa. . . . . April 7, sparks from a locomotive set fire to a great grain elevator on the river front at St. Louis, Mo. The building was destroyed, together with 800,000 bushels of grain. The loss is estimated at $650,000.

ADMINISTRATION.—The President has signed the commission of Frederick Funston as Brigadier General of the United States Army. . . . . Philander C. Knox, of Pittsburg, Pa., has been appointed Attorney General, to fill the office left vacant by the resignation of Mr. Griggs. . . . . The Cuban constitutional convention has rejected the relations insisted upon by the United States, and it will now be necessary to continue the military occupation.

PHILIPPINES.—Instructions have been cabled by Secretary of the Navy Long to Rear Admiral Remey, Commander-in-Chief of the Asiatic station, authorizing him to enlist 500 natives of the Philippines for service on board the former Spanish gunboats and other small vessels which are to be maintained exclusively in the Philippines. Rear Admiral Crowninshield, Chief of the Bureau of Navigation, says that, besides resulting in the Government obtaining efficient service, the employment of natives will spread respect for the American flag and create a strong feeling of loyalty. Reports received from Rear Admiral Remey have shown that Americans, especially those serving in the fire rooms, become quickly debilitated, and it is necessary to send them to the United States or Japan to recuperate. It is believed that the health of the Filipinos will not suffer, because they are acclimated, and if they do become ill it will be an easy matter for them to recover in the Philippines.

FARM AND GARDEN.—The Delaware State Board of Agriculture has decided to send Prof. Wesley Webb, the Board's specialist on diseases of fruit trees, to the Pan-American Exposition, at Buffalo, to find out what sort of an exhibition of agricultural and horticultural products Delaware should make.

A trust or combine has been formed by fruit package makers, which takes in practically all of the large manufacturers.

At Albany, March 29, Senator Ambler introduced a bill providing that all transportation companies within New York State receiving or carrying nursery stock from any point without the State to any point within the State, shall immediately on receiving such consignments, notify the Commissioner of Agriculture of the fact that such consignment is in their possession, giving the name of the consignor and consignee and the point of destination.

The French government has conferred the decoration of the Order of Merite Agricole upon the following officials of the Department of Agriculture for services performed at the Paris Exposition: H. E. Alvord, chief of the dairy division; G. B. Brackett, pomologist; W. A. Taylor, assistant pomologist; M. A. Carleton, cerealist; John I. Schulte, one of the associate editors of the Experiment Station Record. The decoration has also been conferred upon James L. Farmer, assistant director of agriculture for the Paris Exposition.

John S. Harris, well known among Minnesota horticulturists as a practical worker and occasional contributor to horticultural literature, died at La Crescent, Minn., March 24, aged 75. Mr. Harris was born at Seville, O., but went West in 1851, after serving in the Mexican War. He was a pioneer fruit grower and nurseryman, and one of the founders of the Minnesota State Horticultural Society.

Chicago capital has become interested in irrigation of land in Idaho and surveying is in progress near Boise for a large irrigation ditch.

The horse abattoir at Linnton, Ore., which was shut down last Fall, has started up again. About 800 cayuse ponies have been sent in from the ranges, and it is probable that 10,000 will be slaughtered this year. It is estimated that there are more than 500,000 cayuse ponies ranging over the country tributary to this market. Stockmen are anxious that these horses should be driven away to preserve the ranges for cattle and sheep.

The twenty-sixth annual convention of the American Association of Nurserymen will be held at Niagara Falls, N. Y., June 12-14.

Two oleo bills are now before committee in the Pennsylvania Legislature. One, known as the Senate bill, passed that body with but one dissenting vote; the other is the one that the State Department of Agriculture wants. The Grangers, Pure Butter Protective Association and majority of farmers want the former bill. A hearing will be given the oleo people and the pure butter makers this week. The new Road law was reported out of committee this week.

Dr. John A. Myers, head of the Nitrate of Soda Propaganda, died in California recently, after a short illness. He was at one time director of the West Virginia Experiment Station, and was a prominent figure among agricultural chemists.

HENS sometimes eat their feathers through mere idleness, when they are confined in small quarters where they have no chance to scratch. Another reason is lack of meat or animal food in their ration. The remedies are plenty of exercise and some animal food in their diet. Scatter the grain into the litter so that they will have to scratch for it. Some wash the feathers of the neck and breast with an offensive liquid like alum water, tobacco tea or quassia.

Woman and Home

From Day to Day.

Not hers the New Time's lofty lot—
To questions big replying;
She only knows to keep the cot
And soothe the children's crying.

Not hers to stand in temples bright,
Sad strife for strife returning;
She only knows the lamps to light
And keep the home fires burning.

Not hers to move with iron will
In paths of strange endeavor;
She only knows that Home is still
The sweetest name forever!

There are her joys, and there her tears—
A life so sweetly human,
The world shall whisper through the years:
"God bless that little woman!"
—Atlanta Constitution.

*

NEVER use soap in washing windows. Washing soda and kerosene are both better for this use. If the soda is used, dissolve a little in the water, and wash the glass with a flannel cloth. Kerosene is very effectual in removing dust and grime; wet a cloth, wring it partially dry, pour a little kerosene on it, and rub the glass. Chamois first dampened with water and then with a little ammonia, is also good for the same. A good polisher for glass is whiting moistened with tea, to be rubbed on with a rag, and rubbed off again with dry flannel. Heated vinegar will remove specks of paint or plaster, hardened upon the glass. Chamois skins cut and shaped into a sponge-like ball are sold especially for polishing windows.

*

IN making wash dresses, a good effect is gained by taking a couple of little tucks on the inside seam of the sleeve at the elbow, and in this way giving a slightly puffed effect outside. In little girls' guimpe dresses the prevailing style still continues to have a gathered straight skirt and baby waist, cut round in the neck, as before, with a deep ruffle for finishing. In several smart little frocks noted, instead of a little sleeve puff, the armhole was finished with a four-inch frill, which would set out over the sleeve of the guimpe. A child's fine white frock has a very stylish appearance when trimmed with black ribbon velvet of baby width. One little frock for a girl of six or eight, made of white Persian lawn, had two rows of lace insertion at the head of the hem, with several rows of black ribbon velvet between them; the belt was formed of the ribbon velvet, having in the back a puffy little rosette of white satin; a similar satin rosette was put on the bertha or frill around the yoke, a little at the left of the front.

*

WE have had something to say, from time to time, concerning the Sunshine Society, which now claims a large membership throughout this and other countries. Just as charity begins properly at home, so may mental and moral sunshine. Many good people seem to think that man was made to mourn, and that it is a sign of innate frivolity to greet unkind fortune with a smiling face. How often have we eaten solemn meals in unsmiling households, where the slightest attempt at a joke seemed as explosive as a dynamite cracker, and where apparently each member of the family carefully selected the most depressing fact within his experience, as his contribution to the general conversation! In working households, the entire family is rarely assembled save at meals, and it is the plain duty of each person present to make the assemblage as pleasant as possible. We cannot expect hardworked, over-tired people to devote their thoughts to the art of conversation, but they may, at least, avoid "trouble, sorrow, need, sickness, and all other adversity." If we all determine to save up pleasant happenings, innocent jokes, kindly thoughts and interesting things seen, heard or read, as our contributions to the family table, we may reap both mental and physical benefit, for when we eat in company with peace and happiness, then, most surely, does "good digestion wait on appetite, and health on both."

*

IT was recently asserted, at a meeting of a Chicago women's club, that good home cooking is becoming one of the lost arts. The reason offered for this

3755 Tucked Shirt Waist,
32 to 40 in. bust.

pessimistic opinion is that formerly women used to spend their days in the kitchen in constant practice, whereas they now devote their attention to other things. It was also said that the modern gas stove could never equal the old brick oven for baking. The mention of the brick oven brought out reminiscences concerning pie, and one woman present told how her grandmother made 40 or 50 mince pies at Thanksgiving, so as to have enough to last over Christmas. This seemed too much for the belief of some of the modern housekeepers present, but another speaker said that in her New England home they made enough pies at once to last from Thanksgiving to the last of March! They were stored in long rows up in the attic, where they always froze hard, and it was further asserted that there never was a pie equal to one of those that had frozen, and been thawed out just before dinner.

*

A GOOD many intelligent people will sympathize with the point of view expressed by Mr. Jowders, as thus recorded in the Youth's Companion:

Mr. Jowders looked gloomily at the letter to which he had just painfully affixed his signature, and then cast a dubious glance at his wife.

"Do you want to just run this over before I send it to son James?" he inquired; and when Mrs. Jowders shook her head, he hastily folded the sheet, which bore the marks of hours of toil, and thrust it into an envelope, which he sealed with trembling expedition, and then leaned back in his chair with an air of relief.

"I was afeared you'd want to read it, and then most likely 'twould be all to do over again, mother, like the last one," he said. "But I'm glad James wrote he didn't mind a word misspelled here an' there. There's some things I *can* do, but I never could seem to get a good purchase on the system of spelling, someway.

"As I view it," continued Mr. Jowders, "there's some words you can spell by the looks, and some you can spell by the sound; them I can most gen'lly manage. But when you come to spelling by jedgment and main stren'th, my chances are about as slim as they make 'em."

BY desiring what is perfectly good even when we don't quite know what it is and cannot do what we would, we are a part of the divine power against evil—widening the skirts of light, and making the struggle with darkness narrower.—George Eliot.

The Rural Patterns.

The finely tucked shirt waist has a vogue which few styles can rival. The charming model illustrated is of linen batiste, with trimming of needlework, but is entirely suitable for all the thinner, finer washable fabrics, and for soft-finished silks. When made from cotton or linen it should be left unlined, but silks look better and wear better when made over a fitted foundation. The simple lining is correctly fitted with single bust darts, under-arm, shoulder and center back seams. The back proper is laid in two groups of five stralght tucks, the fronts in three groups each, with larger tucks between extending to yoke depth only. The sailor collar is entirely separate and could be omitted if a plainer waist is preferred. The shirt waist sleeves are in bishop style with invisible openings at the back, finished with straight cuffs. At the neck is a stock collar covered with the tucked material. To cut this waist for a woman of medium size 4¼ yards of material 21 inches wide, 4 yards 27 inches wide, or 3⅜ yards 32 inches wide, or 2¼ yards 44 inches wide, will be required. The pattern No. 3755 is cut in sizes for a 32, 34, 36, 38 and 40-inch bust measure; price 10 cents from this office. Shaped and tucked flounces not alone hold the fancy of the hour, they also promise to retain their supremacy for many months to come. The graceful example illustrated combines the favorite points with tucks in a way that means a peculiarly graceful result and can be relied upon to give certain satisfaction. The original is made from satin foulard and is trimmed with lace insertion, overlaid with strips of velvet ribbon; but all silk and lightweight woolen materials as well as such cotton and linen fabrics as batiste, mull, madras, foulardine, lawn, dimity and the like are entirely appropriate to the design, while the trimming can be varied again and again. The skirt is cut in seven gores and is snug

3776 Seven Gored Skirt,
22 to 30 in. waist

and close about the hips, while it flares freely and gracefully below the knees. The fullness at the back is laid in an inserted pleat after the latest accepted style. The flounce is circular, with groups of tucks arranged to meet each alternate point, and is designed to be applied over the skirt in the outline indicated in the pattern, but, if preferred, can be cut away beneath and the flounce seamed to the pointed edge. To cut this skirt for a woman of medium size 11½ yards of material 21 inches wide, 10½ yards 27 inches wide, 10 yards 32 inches wide or 7½ yards 44 inches wide will be required. The pattern No. 3776 is cut in sizes for a 22, 24, 26, 28 and 30-inch waist measure; price 10 cents from this office.

Ironing Table Linen.

Many people have difficulty in ironing table-linen so that it looks nice, but it is really easier to iron it well than ill. In the first place the pieces should be dampened thoroughly—a small whisk-broom makes the best kind of a sprinkler—and then rolled very tightly and left over night. When the time comes to iron them, do not iron them all over, as then when they are folded they will be dry and springy and the folds will not crease well. Fold once, then iron, fold again and iron, and so on. In this way the article is gone over but once and each surface is moist when it is ironed, with the result that when the work is done the linen is glossy and the creases sharply defined. Why do most people fold their tablecloths lengthwise? It is much less awkward to handle them if they are folded across, with the hems together. S. B. R.

A BAYBERRY BAG.—During my Autumn walks I like to gather a few handfuls of bayberries. I tie them up in a piece of strong cotton cloth to use when I am ironing. It is as good as beeswax, and it gives out a delicious fragrance when rubbed on the hot iron. In ironing starched things the iron is very likely to get rough and sticky. A piece of fine sandpaper and this bayberry bag will remedy the difficulty very quickly.

Rural Recipes.

Othello Cake or Devil's Food.—In response to a request for this, Mrs. Josephine Yates send us the following recipe: Part first—Onc cupful of dark brown sugar; one-half cupful of butter; one egg and yolks of two; one-half cupful sweet milk; one teaspoonful soda, two cupfuls flour, measured before sifting; two teaspoonfuls vanilla extract. Part second—One cupful dark brown sugar, one cupful grated chocolate, one-half cupful sweet milk. Grate the chocolate, add milk and sugar, put in a double boiler, and place on the back of stove until dissolved; but do not boil. Prepare this first and have dissolving while preparing part first. To mix part first, cream the butter, sugar and eggs together, dissolve the soda in milk, and add to butter and sugar. Add the flour tablespoonful at a time until all is in, beating lightly. Beat part second into part first and bake in two layers.

Corn Chowder.—One can of corn, one cupful of diced potatoes, 1½ inch cube of fat salt pork, one tablespoonful of onion juicc, four cupfuls of scalded milk, two tablespoonfuls of butter, a teaspoonful of salt and a saltspoonful of pepper. Cut pork into small bits and fry until nicely browned, add onion juice and milk and potatoes, which have been boiled in salted water until tender; corn, salt and pepper. Lct all just come to the boiling point. Put a few oyster crackers in each platc and pour chowder over them. Tomatoes may be added if liked. Hot water may be added if too thick.

Poached Eggs in Glasses.—Add a few grains of salt to the white of an egg (a level saltspoonful to five eggs) and beat until dry; turn into a buttered glass and form a nest on the top for the yolk, which must be kept whole. Put the glass on a trivet, or an inverted tin cover, in a covered dish of lukewarm water, letting the water come to within half an inch of the top of glasses, and let cook until the egg is set and rises in the glass. Do not allow the water which is around the glass to boil. Serve at once. Prepare as many eggs in glasses as there are persons to be served. Dainty and wholesome for invalids.

Baked Beans with Cream.—Soak and parboil a pint of navy beans until half cooked; drain, dash over a quart of cold water, drain again and add the last water (boiling) with two heaping teaspoonfuls of salt, one-eighth teaspoonful pepper, one large sprig of thyme (minced), two tablespoonfuls of beef drippings or the clean, browned trimmings of fat from roast beef, and fried steak may be used instead of the drippings; when beans are cooked tender turn all into a covered bean pot and bake in a very moderate over five hours. Then pour over the beans a cupful of sweet cream and bake an hour longer.

Raisin Pie.—One cupful of nice raisins; wash quickly, cover with boiling water, cook until tender; remove seeds; moisten a cupful of bread crumbs with the water, add one-fourth cupful of sugar, one egg (beaten), one tablespoonful lemon juice and the raisins, cut in two or three pieces each; an upper and lower crust of tender pastry and a satisfactory bake make a most delicious pie.

Kenilworth Pudding.—Two cupfuls of light chopped bread, one-half cupful chopped suet, taking care to free it from all strings, one-half cupful of molasses, one egg, one cupful raisins, seeded or the seedless, one cupful sweet milk, with one-half teaspoonful soda dissolved in it, one-half teaspoonful powdered cloves, one teaspoonful cinnamon and a pinch of mace and salt. Mix thoroughly and boil two hours in a tin pudding dish. Eat with foamy sauce.

He who, having lost one ideal, refuses to give his heart and soul to another, is like a man who declines to build a house on the rock because the wind and rain have ruined his house on the sand. —Constance Naden.

American Opals

In a recent issue of the Saturday Evening Post, it is said that some of the finest opals in the world are now being mined in Washington, Oregon and Idaho. In the last-named State some remarkably beautiful specimens have been obtained from a bed of volcanic ashes, near Moscow, and thousands of dollars' worth of the gems have already been taken out. The precious material is supposed to have been deposited by water when the rocks were still hot, and masses of cinder when broken open reveal the stones, many of which are of the quality known as "noble" opal. This kind of opal is whitish, translucent, and shot through with small and brilliant gleams of all the colors of the rainbow. Gem experts say that the colors described are due to myriads of minute cracks in the body of the stone, the edges of which reflect the light at different angles. Similar tints may be obtained by partially fracturing a chunk of glass with a hammer. Recently a German chemist, by evaporating ether from silica, has obtained beautiful specimens resembling opals and showing all of the exquisite hues.

That opals hardly deserve their unlucky reputation is indicated by the escape of a big jewelry establishment in New York a few years ago from a fire which, while destroying all the rest of the building in which the jewelry establishment was housed, left its quarters and stock untouched—not withstanding the fact that the firm had on exhibition at the time one of the greatest collections of opals in the world. One of the stones in the collection was the great Hope opal, which is said to have been an ornament of a Persian shrine in the seventeenth century. It is oval in shape, an inch long, and represents the sun, with a full face carved on its surface, the rays being supplied by an antique gold setting. It is said that the opal was not considered unlucky in England until the notion was started there by the publication of Anne of Geierstein. On the contrary, it was believed by the ancients to render its possessor lovable and to bestow the gift of invisibility. To jewelers, however, it is liable to prove unfortunate, for the reason that a fine stone will sometimes split in two while being ground. Owing to their peculiar structure, opals easily crack, and it is not advisable to sit in front of an open fire with a ring containing one of these gems.

Mosquito Bars.

If one's men folks are handy with tools, it is an easy matter to have home-made screens which are fully as satisfactory as the boughten ones. Get "clear" spruce an inch square at the lumber yard. The screen frames should be made to fit the windows and always put in the same ones, being plainly marked. Little triangular pieces in the corners make the frame firm. Most of our windows are old-fashioned ones with immovable upper sash, and without weights. The screens are fastened in when the proper time in the Spring comes and then there is no more bother with them till Fall, when they are taken out and packed away for the Winter. The first cost of the wire screen is more than cotton, but it is cheaper in the end, as with care and an occasional coat of screen black they will last many years. It is better to turn in the screen about half an inch when tacking it on the frames, as it is less likely to break off. Tacks a little smaller than carpet tacks are suitable. We have one weighted window, and for this one we have a screen frame which covers the entire window. It fits the outside of the window frame and is held in place by six screws. We can have this window open at either top or bottom without any bother with the screen. This plan would not be practicable, however, if there were blinds on the house.

SUSAN BROWN ROBBINS.

MOTHERS.—Be sure to use "Mrs. Winslow's Soothing Syrup" for your children while Teething. It is the Best.—*Adv.*

A "Swap" Party.

Why not the word "exchange" instead nobody knows, but at all events it has become very popular alike with old and young, says Table Talk. Every guest brings four or five little neatly wrapped and tied bundles. The more misleading in shape as to contents the better. The packages may contain anything from candy to soap, starch, tea, book, handkerchief, sun-bonnet, etc., the more absurd the funnier. Each person recommends his own bundles describing the contents as wittily and in a way to deceive as much as possible. The bargaining becomes very shrewd and merry until all the parcels have been swapped, oftentimes more than once. Then they are opened, the best bargain winning first prize, the poorest compelling the holder to tell a story, suggest a game, sing or recite for the entertainment of the company. The universal verdict—"no trouble and lots of fun!"

A game, suggested by the same authority, is that of numbers. Each guest draws from a basket on the table a slip of paper bearing a number and a half minute is allowed to give some old proverb, adage, fact or rhyme containing the number. If the player fails to respond within the time, a forfeit is required and afterward redeemed in some manner to entertain the company. To make the game more clear the number drawn is ten, quickly follows "ten cents make one dime." If number nine—"Of the muses of old, there were nine we are told." If number two—"Two is company, three is none." If number one—"One, two, buckle my shoe." It seems easy, but one must think quickly to give the required proverb, fact or whatever it may be in the time allowed.

CONSUMPTION

is almost as deadly as ever, although physicians know they can cure it generally, beginning when most of the lungs are still sound, and even sometimes when a great deal of damage is done.

The people don't know it yet. They have been told; but they don't believe it; they don't act on it.

Scott's emulsion of cod-liver oil is one of the principal means of cure.

There are other helps: dry air, sunshine, country, sleep, regular habits, right clothing.

BUSINESS BITS.

IN the manufacture of hand-power cream separators no feature has given rise to so much perplexity as the construction of the bowl. The new bowl used in the Empire seems to solve the problem in a practical and simple manner. The catalogue recently issued by the United States Butter Extractor Co., Bloomfield, N. J., gives full information in regard to its construction and workings. This new bowl is not an experiment, as it has been used several years abroad and has been subjected to exhaustive tests by experts in practical every-day use on dairy farms. We believe it will hasten the day when a separator will be found on every farm where cows are milked.

DON'T wait until your berries are ripe before making arrangements for your berry baskets. You can, as a rule, buy on more satisfactory terms early in the season. Coles & Company, 109-111 Warren St., New York City, handle the output of 27 factories, and they will treat you right.

CORN-planting time will soon be at hand. To get the corn in quickly a good planter is necessary. For those not planting sufficient acreage to afford a two-horse planter the Spangler will be sure to please. It has fertilizer attachment and does its work in a satisfactory manner. Spangler Mfg. Co., York, Pa., is the maker.

THE farmer or chicken raiser who is not familiar with the Victor incubators and brooders should write at once to George Ertel Co., Quincy, Ill., for the 178-page illustrated descriptive book of incubators and brooders. It is "chokefull" of poultry lore. It will tell you how to increase a hatch in almost any machine that is made anywhere near right. There is much in it, too, about hatching and raising ducks, how to build poultry houses, etc.

IT is claimed that the greatest exhibit of pleasure vehicles ever assembled in one building is the current stock of the Columbus Carriage & Harness Co., Columbus, O. More than 2,000 pleasure vehicles of all sorts and styles are shown. The great success of this company is due to their plan of selling direct to the user, thus saving the buyer the entire middleman's profit. A very handsome illustrated catalogue and price list will be sent on application.

Notes by the Doctor.

If in the event of an accident the one hurt should vomit soon thereafter, the injury is likely to prove serious. If a limb be injured so that some deformity results, it is probably either fractured or dislocated. If fractured a comparatively slight amount of force will be required to restore it to its natural shape, but it will only remain so while the force is kept up. Its natural mobility will be found by the one examining it to be the same as ever, except for the pain attending the movement, together with some mobility that is not natural. In the case of a dislocation the mobility of the limb is lessened. There is a fixedness of the joint at the seat of the injury that is unusual and the normal shape or contour of the limb cannot be restored by any moderate degree of force. A flushed face does not necessarily imply the existence of fever; neither is the lack of color a guarantee that fever is not present. In the absence of a clinical thermometer, or the skill requisite for its correct application, the hand of the nurse, if warm and placed on the body of the patient under the arm, will serve the purpose fairly well. Before the clinical thermometer came in this rough test of the temperature was the only one available to us.

Market Briefs.

PICKED UP HERE AND THERE.

APPLE WOOD.—A reader says that a large number of apple trees in his vicinity have been blown down by a storm, and he wishes to know whether the wood can be sold to advantage in this city. We looked this matter up several months ago, but were unable to find any dealer who was willing to pay enough for this wood to warrant shipping it any great distance. At one time it was largely used in the manufacture of pipes, but other woods have taken its place. Makers of tool handles use some apple wood, but most of these factories are in smaller towns and they get all that is needed from the surrounding country, often at a trifle above cord-wood rates.

REFERENCE WANTED.—We are asked to look up the business standing of Chas. H. Lyons, dealer in butter, cheese and eggs, at 264 Greenwich St., New York. He may have a first-class standing and references, but thus far we have not been able to find them or him either. On the ground floor of the number given is a Chinese laundry and a tailor's shop. At the door of the hall leading to the upper stories, is Mr. Lyons' sign and an iron box to receive letters. Every time we have tried the door, however, it has been locked, and signs on the building indicate that the upper rooms are vacant and to let. He is evidently doing a mail business, however, for letters were seen through a crack in the mail box beside the door; but where he receives his goods or has his office we are unable to say.

CUT IN RAISINS AND PRUNES.—The California Cured Fruit Association have struck a hard row to hoe. They have now on hand 900 carloads of raisins, more than the ordinary trade will require before the new crop. The only thing seemed to be to cut prices so as to induce consumers to use more raisins. The present reduction is only on seeded raisins, the price to seeders being made three cents per pound. This would allow retailers to sell pound cartons at about 10 cents. It is thought that at these figures most of the surplus will be worked off, so as to be out of the way of the new crop. Great dissatisfaction is expressed at the manner in which the Prune Association has handled matters. It is said that one-third of the growers have not received pay for the last crop, and the courts have decided that contracts for this season may be canceled. If this decision holds, the Association will practically go out of existence.

DEAD LETTERS.—Every year thousands of letters are sent to Washington as "dead," because of wrong address or removal of person to whom written. All this might be saved if the sender would put his name and address on the left hand upper corner of the envelope. Then the letter would be returned to him if it could not be delivered. There is another reason why this should be done. Suppose a man sends goods to a commission merchant, and is unable to get any reply to his requests for account of sales. If his name and address and a request for return are on the envelope, he may be quite certain that the letter will be delivered or returned as "not found" or "refused." If the party to whom the letter is addressed receives it, or refuses it, and gives the shipper no satisfaction, he then has a case which the postoffice inspector at the general postoffice in this city will take up, and, if fraud is found, the mail of the guilty party will be stopped, thus making things highly uncomfortable for him. The idea is that scalawags must not use the mails to carry on their fraudulent work. Of course these inspectors are provided only to take charge of clear cases of fraud, and under no circumstances would they be employed to settle petty disputes between people. If those who come across clear cases of swindling of this sort would report to the postmaster at the office where the fraud is being carried on, giving full details, it would materially help to make life miserable for those who carry on a scheme of systematic robbery through the mails.

W. W. H.

CONDITION OF GRAIN CROPS.

The wheat and rye, in so far as I can see and learn, have wintered unusually well, and are starting up nicely now. Most of that early sown (before September 25) was hurt in the Fall by the fly, and that is looking bad. A majority of the acreage was sown late; the Winter was very favorable, freezing up early and remaining so. There was light snow in January; February 3, 12 inches of snow, increased a week later to 18 to 20 inches on level. The ground remained covered until about the middle of March. Newly-seeded clover has wintered well also. Prospects are more favorable for wheat than for several years, unless fly gets to work late. In seeding grass on heavy land most sow the latter part of February, or fore part of March when ground is honeycombed; on light soils about April 1, after harrowing thoroughly with spike-tooth harrow. I prefer latter method.

Wolcottville, Ind. J. C. G.

Wheat and rye have gone through the Winter in good condition, and are looking promising now. The acreage of wheat will not be more than 50 per cent. Last Spring grass seeding was generally a failure due principally to grasshoppers. The ground sown to grass then will be put to corn, making a large acreage of corn and a short hay crop. Grass seed is sown with small grains, being harrowed before and after sowing. For the past 10 years it has been almost impossible to get a catch of clover on the prairie and the openings just on the edge of prairie. Timothy is sown generally in October on the young wheat, and the clover the last of March or first of April. J. S.

Lima, Ind.

The Fall-sown grain in this section is looking very well this Spring, and the newly-seeded grass is good. I sow my grain with a drill and always sow the Timothy in the Fall and clover in the Spring, and go over the field with the weeder after the clover is sown, if the ground is dry enough for the weeder. The smoothing harrow is good, but the slanting tooth will destroy some grain in turning around at the end of the field. In order to get a good stand of grass I should first plow the ground and then harrow it very thoroughly to kill all weeds; then sow 600 pounds of some good grass fertilizer per acre broadcast, and harrow it in; then 12 or 16 quarts of Timothy about August 25, and go over it with the weeder. E. P. B.

Columbia Co., N. Y.

There was a very small acreage sown to Winter wheat last Fall in this county (Menard), on account of Hessian fly and chinch bugs. Wheat wintered well and is looking fine. Rye looks well, but small—not much grown in this vicinity. Clover seeded last Spring is looking fine. Clover is generally seeded broadcast on Winter wheat or rye, and when sown late in March or early in April, and the ground is dry enough, is generally harrowed in, but when sown earlier, and ground is cracked, the rains and action of frosts cover the seed sufficiently. Considerable clover was seeded in this vicinity last Spring with oats, mostly early oats, and the clover is looking fine. Timothy is generally seeded in the Spring on Winter wheat. Our soil is mostly black loam. A. D. A.

Sweetwater, Ill.

Winter wheat and Fall seeding are looking remarkably well in this vicinity, and also in adjoining towns, as far as I have observed. With the same showing 20 years ago we certainly would have expected a yield of 35 or 40 bushels per acre. We sow our wheat from September 10 to October 1, and sometimes later, now that fertilizers are almost invariably used. Timothy is sometimes sown by seeder attachment on drill, or within a week or more by wheelbarrow sower. All varieties of clover are sown about April 1, and if favorable weather follows we are almost sure of a good catch. I sow four quarts Timothy, three to four quarts Medium, and 1½ Alsike clover per acre. This makes a choice quality of mixed hay for one or two years, after which clover dies out, leaving a strong Timothy sod that will cut a good crop of hay for six or eight years if not pastured too close in the Fall. Our soil is clay loam.

Lima, N. Y. W. H. D.

The Winter this year has been an extremely favorable one for Fall-sown crops. The prospects now are that there will be a large crop of Winter wheat this coming season, in this section of Illinois. Wheat never came through the Winter here in better condition. Apparently, the Hessian fly will not trouble us this season. There were many of these flies last Fall in all of the wheat sown in this section, but wheat in which they abounded last Fall, when taken into warm quarters this Spring, fails to bring forth any flies. Our crop was practically ruined last season by this pest, but this year it has seemingly disappeared from some cause. If one variety is in any better condition than another it is the Harvest King at the present. This variety is recommended by our experiment station. Fall-sown Alfalfa, clover, Timothy and Red-top are also in excellent condition. Those who tried the Clark method of seeding last Fall think it a good one. I believe that it will be more largely followed yearly. The general practice of farmers of this locality is always to make a good seed-bed for all grain and grass seed sown. Our soil (bottom land) has just enough sand in it to make it friable, and we rarely fail to get a good stand. A common expression of farmers here is: "Do half of the tending of your crop before it is planted!" Little rye sown here, but this looks well. Corn is our staple crop with wheat a very close second. R. O.

Bluffs, Ill.

The Great Value

and the marvelous healing power of

Veterinary Pixine

has never been made more manifest than when in emergency a speedy and permanent healing ointment is urgently needed.

Apply it, rub it in on bare spots, inflammatory swelling, old sores, scratches, grease heel and speed cracks. It penetrates and soothes, and the horse grows well as he toils throughout the day.

Absolutely antiseptic—scientific, unfailing. Indorsed by stock-raisers and trainers throughout the United States and Europe. Investigate; money back if it fails.

2 oz., 25c.; 8 oz., 50c.; 5-lb. pkge., $4.

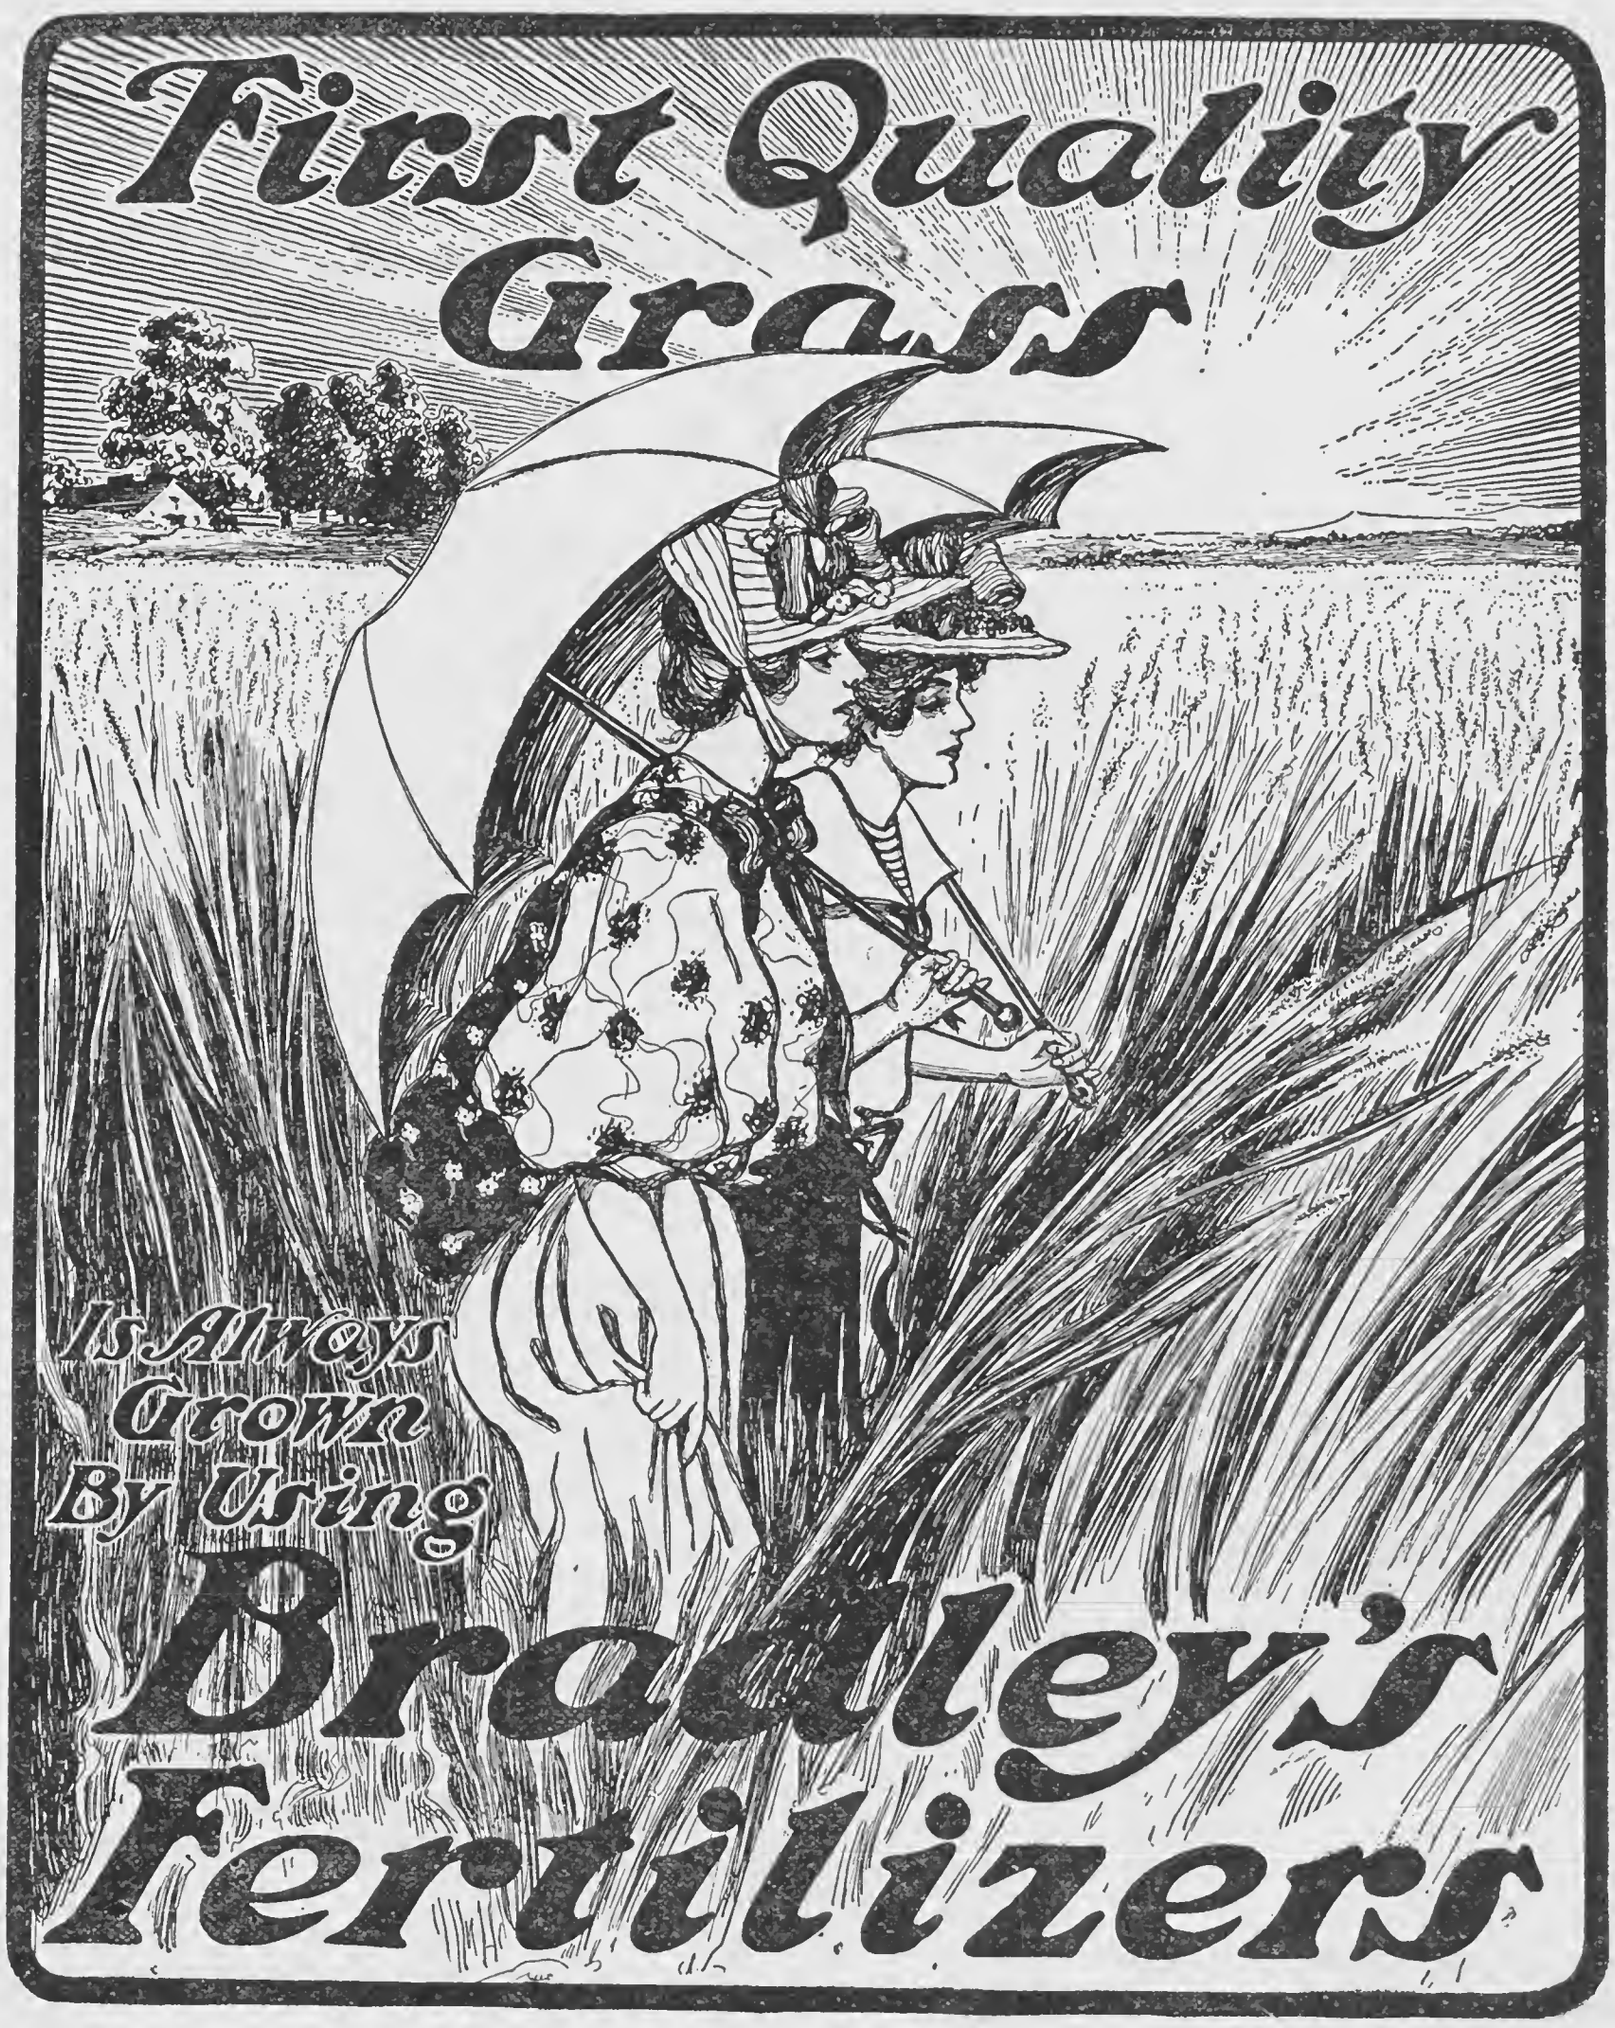
Why Not

Preserve Wheat and Rye Straw Straight Bound in Bundles?

Please your customers by saving barn room and ease of handling straw. We make a machine that we guarantee to thrash wheat perfectly clean and not bruise or break the straw, that will bind it again in bundles. The same machine thrashes rye and preserves the straw, straight, bound in bundles, and is also changed in 15 minutes to a spike-tooth oat and wheat thrasher Send for Catalogue B. Free

GRANT-FERRIS COMPANY, Troy, N. Y



The Mapes Corn Manure.

This is a complete manure for corn, and requires the use of no other fertilizer. It contains all the ingredients required to secure the full development of the crop, both in abundance of stalk of improved feeding quality, so important in ***ENSILAGE,*** *and also in yield of well-filled deep-kerneled ears. Also adapted for Clover, Turnips, Etc*

To Grow Paying Crops of Corn and Bring Up Poor Land.

This manure is adapted for ***BROADCAST*** *use for growing Corn. Many light, sandy lands, "poor as poverty," like the Hartford "Plains," have by broadcasting three to four bags per acre of this manure, been brought up into good condition for grass or for any crop, and made to pay from the start.*

Read **"TWENTY YEARS AFTER"** for practical results at Newington, Conn, on seven acres of "the poorest piece of land," with the **MAPES CORN MANURE** (two tons on the seven acres broadcast harrowed in), two years in succession; then Potatoes (three tons of the Mapes Potato Manure), two years; then Oats (54 bushels per acre); then heavy mowing of hay. This land at first was so poor that nothing but pigeon grass and dewberry vines grew on it.

Lands otherwise practically worthless, made to produce, by annual applications, paying crops of corn from the start after liberal figuring for labor, interest and taxes, and brought up equal to the good lands. This cannot be done by using "a little in the hill," like a superphosphate, "to start the crop with."

The Great Corn Contest of the American Agriculturist.

Crops 213, 119 and 95 bushels each; grown on one measured acre exclusively with the Mapes Corn Manure.

Of this great crop, 213 bushels shelled corn, grown in Yates County, N. Y., with the Mapes Corn Manure (800 pounds per acre) exclusively, the American Agriculturist says: "If we allow only $15 as the value of the tops for fodder, and make no account of bottom stalks, the cost comes within 20 cents a bushel (shelled corn)."

The Largest crop grown with fertilizer, other than the Mapes (45 crops in all) was 84 bushels (chemically dried, 60 bushels.)

Some Large Crops Grown with the Mapes Corn Manure, and reported in the Agricultural Press:

1,040 bushels of corn (ears) on less than 4½ acres, equal to 233½ bushels, or 116¾ bushels shelled corn per acre, grown on farm of Rural New-Yorker, with the Mapes Corn Manure.

Ninety bushels (shelled) with 500 pounds per acre. 150 bushels (shelled) with 600 pounds per acre. Value of the grain alone over five times as much as the cost of the fertilizer.—American Agriculturist.

Eight hundred and fifty-six bushels (ears) on four acres. 159.37 bushels on one acre. 125.37 bushels on one acre. Nothing used but the Mapes.—Rural New-Yorker.

On two acres 600 pounds of Mapes alone, broadcast, 198 bushels shelled corn. On three acres, same fertilizer, same quantity. 489 bushels (ears). Grown by Dr. Henry Stewart.—New England Homestead.

One hundred and eighty bushels of ears per acre; shelled, 98.45 bushels. 2,058 bushels (ears) on 16 acres. Only Mapes (800 pounds per acre) used.—Connecticut Farmer.

The Mapes Formula and Peruvian Guano Co., 143 Liberty St., New York.

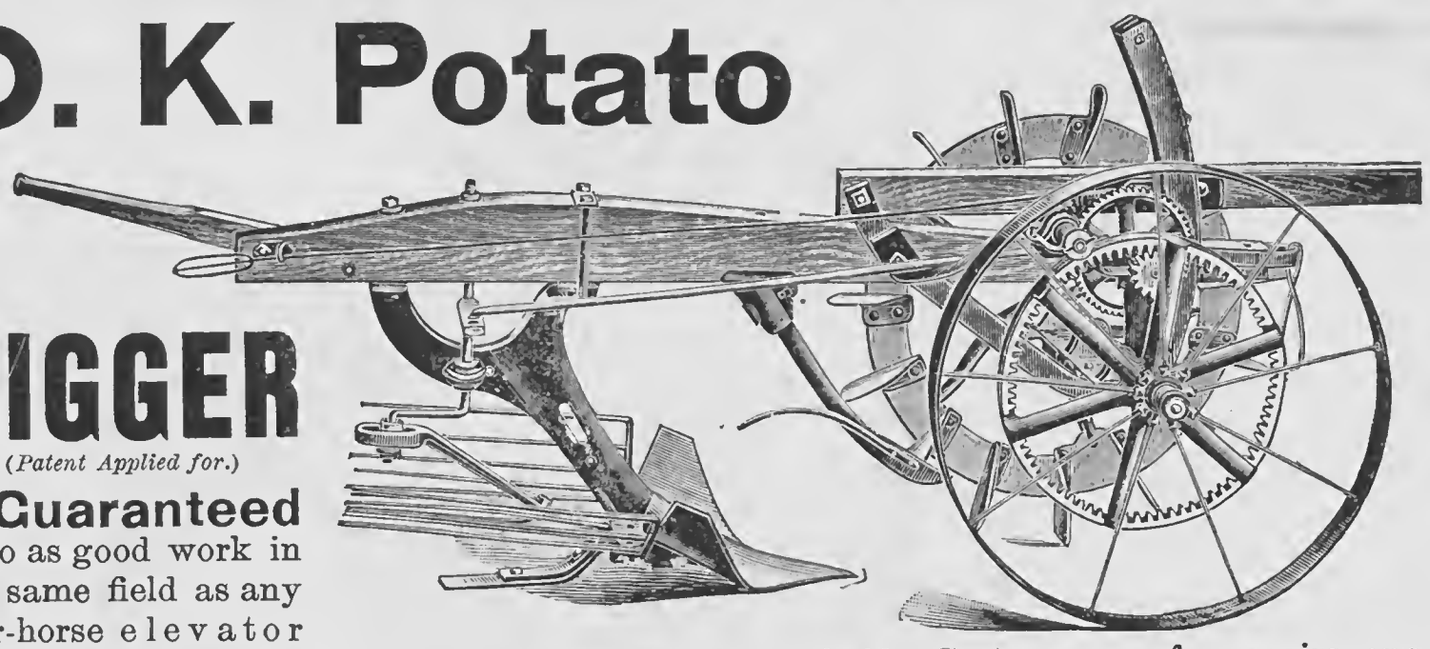
O. K. Potato DIGGER



(Patent Applied for.)

Guaranteed to do as good work in the same field as any four-horse elevator digger on the market. Price one-half. Draft one-half. Cost per year for repairs, one-fifth. Guaranteed to dig as clean as a man can with a fork. Will make digging potatoes as easy, simple and inexpensive as cutting grass. Would such a digger please you? Will you buy such a digger? WE TAKE ALL THE RISK—unsatisfactory work in your field means no sale. Every farmer who grows five acres or more of potatoes is interested. We wish to hear from all such.

ESSENTIALS OF SUGAR-BEET CULTURE.

GREAT CARE IN PREPARING THE SOIL.

Special Needs of the Crop.

SOME PECULIARITIES.—The first thing is to learn the habits of the plant. It is different from anything else I have ever tried, and does not appeal to the average grain and stock raiser. Sugar beet seed germinates slowly, and the young beets make but little growth for a few weeks. One cannot wait for them to be of good size before cultivating, as the weeds will be too large. They grow into the ground, and the top root may be two feet long, which enables them to withstand drought and the effects of the weeder without injury. Breaking off the leaves is often a benefit, and abroad they are picked off and fed to the stock. The effect is to cause greater root growth, and for this reason one need not handle them as he would eggs. It is intensive farming, and the most successful, so far, are foreigners, market gardeners and vegetable growers, who understand the necessity of, and saving in thorough preparation before sowing the seeds.

SUITABLE SOIL.—A soil which is loose, and 10 or more inches deep before the harder subsoil is reached, will grow sugar beets if naturally drained enough for crops of corn or potatoes. Fields approaching in color and texture a black muck swamp which have clay loam, or sand enough to make them hold together, so as to form a firm seed bed, are nearest our ideal, but heavier clay loams, with more labor and proper care produce fine yields. Dry hills, stony, shallow soils and heavy clays, are not suitable, and gravel is uncertain. Perhaps the best soil is a dark, sandy loam. Stone and uneven surfaces do not prevent growth, but are objected to because of the inconvenience of working the crop. Sod ground plowed deep, and preferably, in the Fall, will answer, but my first choice is a corn, potato or buckwheat stubble, and it is all the better if it was highly manured. Subsoiling does not pay where one can plow nine inches deep, and the bottom of the furrow is not hardpan or hard clay. Clay loams with solid subsoils are benefited. The concensus of opinion indicates that farm manure is the best fertilizer for large yields, and phosphatic next. Too much use of nitrogen is often an injury.

A GREEN CORN SANDWICH FOR MASSACHUSETTS COWS. FIG. 123.

A PERFECT SEEDING.—The profit of the crop depends on getting a perfect stand. They are not worth enough to pay to transplant; and vacant spots, if seeded the second time, give indifferent results. To insure plenty of plants, use plenty of seed, and have the best possible seed bed. The profit of the crop depends also on the cheapness of growing. Thought and care must be given at every point to reduce cost. As soon as the soil is dry enough to work plow and harrow the field. When the weeds have sprouted, harrow and kill them. In a week harrow again. Do this as many times as possible before time to sow, which in this section is May 20. The last two workings harrow lightly. Weed seeds which are three inches below the surface will not grow, and should not be brought up to the top. The aim is to firm the seed bed, and free it from weeds before the beets are sown. All things considered, a grain drill is the best and cheapest machine for seeding with. Use 10 to 14 pounds of seed per acre, and have the rows 21 inches apart, or every third tooth. Let the commercial fertilizer run in all but the seed tooth, and, if applied in small amounts, in all. Care must be taken not to get the seed too deep, and we roll the ground before seeding, so the wheels will run even, and not sink so deep. Cover the seed to the depth of one-half to 1½ inch, according to the state of the soil. If very dry and rains not probable they should be planted deeper than if soil is moist. Should a crust form, or weeds start before the beets prick through to the surface, use the weeder, going once across the rows, about four days before the beets appear. This crust, if hard, especially on clay loam, must be broken.

MUST NOT BE CROWDED.—Prompt action in thinning will save many days' labor, and the blocking out with the hoe can be done faster before than after the first cultivation. While the beets are in the second and third leaf run the weeder across the rows and tear out half the beets. In three days, if there is a good stand, use the weeder the second time, and then cut out seven-inch spaces with a hoe, leaving as small a space as possible in the block, which will contain from one to four beets. With a narrow hoe cut out all but the most vigorous plant in each block. The plants would then average eight inches or more apart. In blocking out save vigorous plants, even if spaces are not regular, but be sure to give space, for a large growth. With large beets the yield will be greater, and more easily and cheaply handled. By prompt action in thinning, nearly, if not all, pulling out by hand can be avoided. The seed required costs but little, and plenty should be used (especially with large drills which may cover a portion too deep) to secure a continuous row. If the drill tooth is set to point back as far as the angle will let it, the neck-yoke straps lengthened so as to drop the end of the tongue lower, and the tooth chains are drawn up a few links and tied, there need be no trouble to sow at any depth desired. Planet Jr. steels an inch wide can be purchased for eight cents each, and their beet-hoe teeth for 25 cents. Either of these can be attached to any cultivator, and are all the tools needed. Two or three cultivations following the thinning at intervals of a week, should be sufficient, and work done on them after that time usually adds nothing to the yield unless Summer weeds or a crust comes on.

ECONOMY IN HARVESTING.—With the team walking, one horse each side of the row, run the land side of the plow close to or a little under the beets, and a boy following can lay the beets over out of the way nearly as fast as the team will walk. By using a subsoil plow a number of rows can be loosened ahead before any are laid over. The beets should be laid with the tops all one way, and several rows laid together. A low table or bench is placed by the side of the windrow, on which two men can work facing each other. A sharp hatchet is used for trimming, and one stroke is sufficient. Where the beets are laid in regular order there is no turning or pulling them out of a heap, and one gains much time. Where the beets are loosened ahead the boys place the beets directly on the table. The beets are thrown in piles, covered with tops and drawn directly from the field to the car. The tops should be piled immediately in small piles and drawn as wanted for feeding. They will heat and spoil in large piles, or in the barn.

C. E. CHAPMAN.

OHIO GRASS AND GRAIN.

Fall-sown wheat and rye in this part of Ohio stood the Winter very well, and are now looking fine. Fields sown after September 20 are now green with the growing grain, and give promise of an abundant harvest; clover sown last Spring made a good growth, went into the Winter in good shape, and in going over my fields I notice very little of it raised out of the ground by freezing. Where the land was well tile-drained there is none heaved up at all. While we had no great amount of snow, there was enough to protect the growing wheat, rye and grass. I run my farm on the four-year rotation of crops, viz., clover, corn, oats and wheat; sow clover seed on the wheat, and have had the best success, or rather have had best results, sowing seed the latter part of January and first of February, should there be no snow. I would not like to sow on snow; the melting of it causes the seed to bunch. It floats together too much. If I cannot sow in January or February I wait until the last of March or first of April, in order to avoid the freezing weather that we often have at that time. That catches the seed when germinating, and not sufficiently rooted to stand the exposure. I am guided by the conditions I have to meet. I prefer the early seeding; use the Cahoon broadcast seeder, and sow from five to six quarts of seed per acre. I usually mix about eight quarts of Timothy seed with each bushel of the clover seed; thus both are sown at the same time. If we want a permanent pasture we sow more Timothy; in time the clover gives way to the Timothy, and the Timothy is crowded out by the Blue grass. With us here it is useless to sow the Kentucky Blue grass, from the fact that the native Blue grass supersedes it. The native Blue grass is indigenous to our soil, and will cover a field in three or five years, if left to itself and not disturbed by cultivation.

R. C. P.

Camden, O.

MY plums are mostly Lombards, and they rot badly, but bear regularly. The blue plums are preferred in the market. I think the Abundance is the best of the Japans; the Satsuma does no good for me yet. P. H.

SHALL WE THIN STRAWBERRIES?

The Demand for Large Fruit.

Do you know of any case where strawberry growers have cut off the fruit or blooms for the purpose of obtaining large and perfect fruit? One of our readers has had more or less trouble with his plants setting a large amount of bloom and producing only a heavy crop of small inferior berries. He says that as it pays to thin out apples, plums or peaches, it might also pay to thin out or cut off a portion of these fruits, hoping thus to obtain a large size for those left on the plant. Do you know that this has ever been done? Do you think that it would pay where one has a market for fine berries?

Thinning blossoms is done more particularly to obtain exhibition berries, not only to get larger berrics but those of better shape. The thinning should be done after the berries are formed, cutting out the small and deformed ones. I do not think the thinning is done much for market purposes; a liberal supply of manure with lots of water will pay better for the market. You must give the plants plenty of room. After the berries are well set watering with liquid manure will help out the size of the fruit. Water has more to do with the size than any one thing. If people should set out a few of different varieties they would soon learn the best kind for them to adopt.

Weston, Mass. S. H. WARREN.

As neither variety nor method of culture is given it is difficult to suggest a remedy. With us the large fruited varieties rarely set more specimens than they carry through to perfection in a favorable season. In hothouse culture the fruit is always thinned, but I feel sure it would not be profitable in a commercial sense in field culture. I think the best way the inquirer can attain his object is to keep his plants thin either by using a very narrow row or thoroughly thinning the plants in the wider row if he grows them so. We find that the largest and best fruit is produced upon strong, well-developed plants as near 12 months old at the time of fruiting as possible, and our smallest and most numerous on large stools or hills with the runners cut. F. G. TICE.

Oswego Co., N. Y.

I have no experience on this particular line, but I have no doubt it would bring the desired effect. I am inclined to think, however, that the remedy would cost more than the patient would sell for. A far more practical plan would be to plant varieties that do not overburden themselves with fruit or manure and irrigate to bring the immense loads of fruit to perfection. Irrigation would scarcely be more expensive, and would at least double the crop. It would be a tremendous job to thin the blossoms on an acre of strawberries grown in the matted-row system, or even if grown in hills. Furthermore, this would have to be done every year. I would advise that if the market is good enough to justify the expense of thinning to improve the quality, the more practical thing would be to irrigate. W. F. ALLEN.

Maryland.

This would not be my way to produce such results, and I do not think it would pay. There are ways that are practicable and will pay. Your correspondent undoubtedly has too wide rows and too many plants in the rows. Grow the plants in narrow rows, set plants three feet apart in the row, and fertilize liberally, and enough plants will grow to make all the row needed for good results. If the trade will pay for the extra trouble set plants three feet apart in the row and set first runner plants in a single row about six inches apart, and take off all runners that start on the plants afterward. Rows may be two to 2½ feet apart. To sum up the matter, reduce the number of plants in the row, and feed them liberally. This is the key to success, provided they are given proper cultivation and climatic conditions are favorable.

Dutchess Co., N. Y. WALTER F. TABER.

I have never seen the fruit or blooms of strawberries thinned for the purpose of obtaining large, perfect fruit, neither do I think the practice would pay, even if it would accomplish the desired result, because such work could only be done by the most careful workmen, and must be done at the very busiest season of the year, when such workmen cannot be spared. It is easy to grow large strawberries for a near-by market without thinning—this is the method I followed for a number of years very successfully: Select perfect-flowering varieties; these do not set too many fruit stalks. Plant in the Spring in rich, well-prepared ground, and cut off *all the fruit stalks* the first year as soon as they are in full bloom (this work can be done by boys and girls very cheaply). Keep clean and well cultivated during the entire season. As soon as the ground has frozen sufficiently hard to bear a horse and cart, cover the entire surface of the ground with fine horse manure at least two inches deep (I use manure from a livery stable bedded with sawdust); allow this mulch to remain on the ground. The plants will grow right up through it in the Spring; the Spring rains will wash it thoroughly, leaving a surface of clean sawdust for the berries to ripen on. The nitrogenous manure produces a large stalk with rank foliage, the mulch holds the moisture, and the result is large berries. Of course strawberries grown this way will be soft, and cannot be shipped long distances, but will command high prices in near-by markets. Ninety per cent of the strawberry is water; the heavy mulch recommended above, placed on top of a soil well-filled with humus, will furnish a large supply of water to the crop, and in my opinion is cheaper and better than thinning the blooms or fruit on an unmulched patch. GABRIEL HEISTER.

Pennsylvania.

ADVERTISING AT FARMERS' INSTITUTES.

Farmers' institute programmes often have advertising matter printed on them, the result of solicitation among local business men. In recent attendance at a local Indiana institute the writer found a scheme new to him, that had been tried, of having farmers advertise their goods for sale on the programme instead of town merchants. The accompanying illustration, Fig. 124, shows a page from this programme. The idea is an excellent one and should be taken up by farmers. They not only help support the institute by doing this, but they also let their friends and neighbors know what they have for sale.

COW LUNCH IN THE PASTURE.

The practice of "soiling" or cutting and carrying green crops to stock is increasing, as farmers realize how much more food can be obtained on an acre in this way. A few dairymen grow a great variety of crops, so that from the earliest rye until the latest barley and peas there is always a supply of green food. Many, however, are satisfied with rye, corn and millet. No doubt corn is the best single crop for this purpose, but it should be pieced out at either end of the season, and in order to do this crops must be grown that will stand the frost. Our picture, Fig. 123, shows a Massachusetts hillside pasture in which the cows are taking their green lunch. Our western readers will smile at the rocks which stick their noses out of the soil of this pasture! The cows know their business, however, and are not afraid of the stones. They will put that corn sandwich just where it will do the most good. Mr. Nichols, who owns the cows, writes this note about the corn:

"This corn that the cows are eating grew in a field beside the pasture, and I had only to throw it over the fence. I do not advocate always feeding the corn to the cows in the pasture, as the stronger cows get more than their share; but when it is first large enough to use, it is so tender they will eat it up clean, or if any is left they will finish it next morning. It is very convenient to do this when the cornfield happens to be alongside the pasture. I generally plant about two acres of fodder corn for Fall feeding, and have it ready for use about August 1, when the pasture begins to dry up. I feed it once a day, giving each cow all I can possibly lift with both arms. Except occasionally, as you see it fed in the picture, I bring it to the barn with a wagon, and have it for the cows when they come from the pasture at night. I had on these two acres last Fall about five tons. It grows from six to 12 feet high. I feed it green until the frost takes it, then cut, bind and stook the balance. I use western yellow corn for seed. Some of the readers may think that it is a great temptation to have the cornfield beside the pasture, and the cows I had corn on three sides of the pasture, and the cows did not break into the corn any more than they did into the mowing or road. I generally keep my eye on them, so they never do any great damage. Once, when some berry-pickers left the bars down the cows passed through the cornfield and never molested it. They passed through two other fields into a field of cabbages, where they filled themselves in grand style."

SPRAYING TREES IN FEBRUARY.

A Call for Information.

On page 207 Edwin Hoyt says: "Spray in February with Bordeaux Mixture." Is this sound advice, or a slip of the pen? Imagine getting out the spraying rig and attempting to spray an orchard in snowbanks three feet deep, to say nothing about the frosty air and howling winds incident to the season. But this is not the point. Why the need of a fungicide in February? We read that the fungous diseases are most active in damp muggy weather and are practically dormant through the Winter, or until about the time the buds begin to swell in Spring. But, granting the need of a fungus spray in February, why the lapse of from eight to 10 weeks, when the blossom buds appear, before Mr. Hoyt advises the second spraying? Be it remembered that Bordeaux Mixture is not a cure, but only a check to fungous growth, and if there be need of a spray in February why not a similar need every two or three weeks thereafter until the blossoms appear? Mr. Hoyt further advises the application of Paris-green "after the blossoms fall and fruit is well formed." To beginners and all looking for advice on the subject we urgently advise especial heed of the first part of the clause, "after the blossoms fall," and not wait until "fruit is well formed." Our best scientists have observed that from 75 to 85 per cent of the worms of the Codling moth enter the apple, that is, take their first meal, through the blossom end. Therefore, to make the application most effective, here is where the sprayer should lodge most of the insecticide. Now then to lodge the spray in the blossom or calyx end of the little apple it must be done within a week after the blossom falls, or it will then be too late, as close observers have noticed that immediately after the blossom falls the calyx cup in the miniature apple begins to close up, and is almost completely closed up in a week or 10 days. It is obvious, then, if we wait until the "fruit is well formed" before applying the poison our opportunity will have passed.

In the light of our experience, and in that of other orchardists with whom we are conversant, we would make the first application of Bordeaux when the buds first show signs of swelling, which is in this latitude about April 10 to 15; the second when blossom buds show red ends; (we apply poison also with these applications for bud moth, tent caterpillars, etc.), the third immediately after blossoms have fallen; and fourth about 10 days or two weeks later. These are not iron-clad rules, but are modified according to the weather and season. Some of the best orchardists omit the first application named, while others substitute this for the second, thinking it more important. We make these comments not in any unfriendliness to Mr. Hoyt, but to bring out whatever is to be learned on the subject. What all good orchardists want to know is *just* when and *only* when it is necessary to spray. W. A. BASSETT.

Seneca Co., N. Y.

Mr. Edwin Hoyt Talks.

That is quite right, Mr. Bassett. If you do not believe a thing which you see written, or do not understand it, then pitch in and dress out the writer. That is the way to draw out the discussion. But you are doing well, very well. You spray your trees four times in the season. That is much better than very many orchardists do. If that accomplishes all to be desired in spraying then do as you are doing; I have no criticism to make. I made no slip of the pen, however, when I said spray the apple trees in February. I am advising from my section, where we seldom have "snow banks three feet deep or howling winds" in February, so that there are not some days in the month fitted for orchard spraying. If in the latitude of Mr. Bassett it is impracticable to spray in February, then do it as soon as it is practicable. It is not absolutely necessary to do it in February, but it is advisable to do it some time while the trees

are in a dormant state. Mr. Bassett says: "We read that the fungous diseases are most active in damp, muggy weather and are practically dormant through the Winter, or until about the time the buds begin to swell." Exactly. But where are these dormant fungus spores? We read, also, that they are fastened to the underside of the loose or partly lifted bark; in the crotches of the limbs where any foreign matter like small leaves, pieces of bark, moss or other dirt may lodge, and in various other places where one's eye would not detect them; that while the tree is dormant a much stronger solution of sulphate of copper can be used in spraying than when the tree is in foliage, and that by spraying in February or March (as best suits the locality), the destruction of these dormant spores, so far as the tree sprayed is concerned, is sure; for if the spraying is thoroughly done, every part of the tree can be hit with the copper solution. Again, we also read that it is wise to rake up all fallen leaves lying under the trees and burn them, as they also harbor or contain myriads of these fungus spores which "lie dormant until about the time the buds on the trees appear." Do not, however, try to burn them when covered with snow or the howling winds are raging. It would not be practicable.

There is no need of spraying but once in the Winter, as one spraying, if thoroughly done, will be sufficient, until the warm weather comes and the undestroyed fungus spores wake up and make ready to do their Summer work. About this time the tent caterpillars hatch out and commence their work of eating the little leaves as they push out, which is about the time the blossom buds show some red. Then spray the second time with the regular Bordeaux Mixture with five or six ounces of Paris-green added to 50 gallons. This spraying will destroy the caterpillar and serves to keep in check the fungous. The next or third spraying use the same mixture as the second, and spray after the blossoms have fallen and the fruit is formed (I will leave out well, as it was not properly interpreted); this spraying will not only destroy many of the Codling moths, but the Canker worm, which (if it come), appears about the last of May. The fourth spraying, in about 10 days later. Now I do not see that Mr. Bassett and myself are very far apart in this spraying business. He sprays four times, twice before and twice after the blossom falls. I advise for first spraying in February. He sprays first about April 10 or 15. In February we have many pleasant days, and nothing driving in our work. In April I am in the middle of plowing, sowing, planting, etc. Time is with me worth more in April than in February. Is the spraying any more effectual in April than earlier? Not at all, but rather the strong solution of sulphate of copper used (say double the strength used when the foliage is out), has longer to work and act upon these "dormant" spores than if used six or eight weeks later. If Mr. Bassett has no other farm work to do than attend to his orchard (as I believe no thorough and large orchardist should have), then spray the first when most convenient to do it, yet I fully believe if done a month earlier than he does it, it would be rather more effectual. EDWIN HOYT.

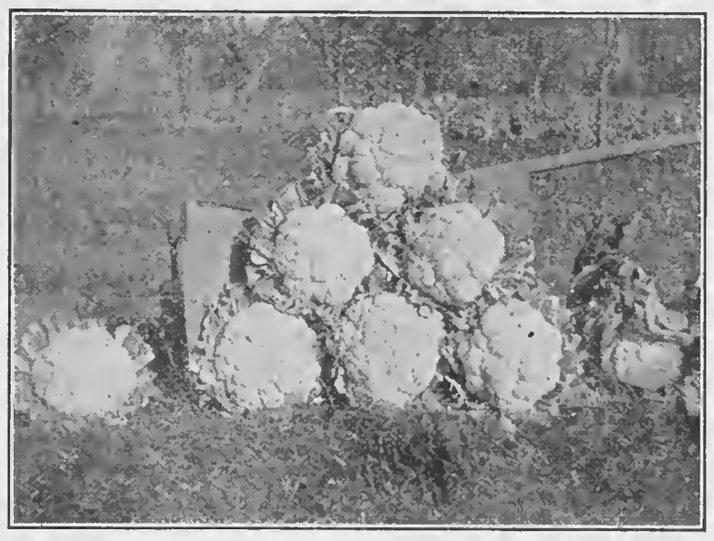
Fairfield Co., Conn.

THE STAYMAN AND SOME OTHER APPLES.

The Stayman apple, which is referred to in THE R. N.-Y., March 23, has wholly superseded the old Winesap here, being (as Professor Van Deman states), equal to it in every respect, and superior in some. As between Stayman and York Imperial, the latter has a little advantage in the red being rather more brilliant, but in quality it is somewhat behind Stayman, and in the growth of the tree a good deal behind; while the peculiar oblique form which York Imperial usually assumes is against it as compared with the smoothness and symmetry of Stayman. A choice early Winter apple about which not much has been said is Evening Party. It is a most beautiful fruit, bright, dark red, over the whole surface generally, with a bloom, and is just the right size for a dessert apple. The texture is very tender, and the mingling of sweet and acid—the latter slight but distinct—makes it welcome to young and old. It originated in Pennsylvania, but was received here (20 years or more ago) from the late I. D. G. Nelson, of Fort Wayne, Ind.; a man who had a just appreciation of fine apples. The tree is a beautiful, upright grower and a profuse though somewhat tardy bearer. Another choice apple which usually lasts until the middle or end of April, is Stuart's Golden. It is an Ohio variety, having originated in Fairfield County, about 40 miles southeast of Columbus. In color it resembles Grimes Golden, but it generally has a blush; and in quality it is worthy to stand with any of the varieties mentioned. The tree is a vigorous, spreading grower, and an early and profuse bearer, not dropping its fruit as Grimes does. It was named from the family in whose orchard the original tree grew; and Mr. Downing placed it in his large work, "Fruits and Fruit Trees of America." The outline there is below the usual size.

About the only kind troubled with twig-blight here is the fine old Fall Pippin. Its place can be taken, however, by the excellent variety raised by Dr. L. S. Mote, of Miami County, Ohio, and named Celestia by Dr. John A. Warder, author of "American Pomology." It is less acid than Fall Pippin, and not quite so desirable for the kitchen, but better for eating out of hand. It is about the same color as Fall Pippin, and many specimens closely approach it in size. The tree of beautiful, vigorous growth and a good, but not very early bearer. Lankford, recently introduced from Maryland, hardly sustains its reputation thus far, but it may do better after a further trial. Tompkins King and Tolman Sweet are comparatively of no account here. The best Winter sweet apple is Broadwell, a variety said to have originated on the Ohio River above Cincinnati. It usually keeps until April. Baldwin is generally on the ground at picking time, and beginning to decay; too far South of its native locality. The same may be said of Palouse, the beautiful variety from the Valley of the Columbia, in eastern Washington, where it keeps until April, but ripens here in September. It is thought to be a seedling of the old Bellflower. Two others, known to be seedlings of Bellflower, Marshall (from California) and Dickinson (from near Philadelphia), are promising, but have not borne sufficiently yet to fix their standing. Arkansas Beauty is superior to Arkansas Black, though hardly as brilliant in color as represented though still a "beauty." It is a very promising apple, and bids fair to be a very early bearer. One three-year-old tree (which had not been moved), bore three apples in 1899, and last season it bore no less than 13. R. J. BLACK.

Fairfield Co., Ohio.



THE MATTITUCK CAULIFLOWER. FIG. 124.

SOME COW-PEA FACTS.

Are you still advocating the use of cow peas?

Certainly. Reports are nearly all favorable.

What soil are they best adapted to?

The lighter, poorer soils of the farm. We would not sow them on good corn ground. Put them on the poorest field in the rotation.

ROPING A COW'S TAIL. FIG. 125. SEE PAGE 319.

Do you advise their use as fodder or hay?

No, not in the North, though some northern farmers have found them very useful. At the New Jersey Station an acre of cow peas gave 16,000 pounds of green forage per acre, or 384 pounds of protein. This would equal the protein in 2,500 pounds of wheat bran. At the Nebraska Station cow peas were used as a pasture for cows. It was found that an acre of cow peas produced more milk than an acre of sorghum fed under the same conditions.

What would you plant cow peas for, if not for hay?

To plow in as manure, or to make a hog pasture. In an inclosed field near the house the hogs might run on the cow peas and eat them to advantage. Usually such fields will produce corn or some better forage crop. We plow the cow peas in as manure.

What are they worth as manure?

At the Louisiana Station it was estimated that the leaves, stems and roots of an acre of drilled cow peas furnished 108½ pounds of nitrogen, 25 pounds of phosphoric acid, and 123 of potash. The yield was below the average.

What does that mean?

It would require more than 10 tons of average stable manure to provide this amount of available nitrogen and potash.

Suppose the crop had been cut for hay?

In that case, most of the nitrogen would have been taken from the field. The roots of the cow pea are comparatively small. The nitrogen, which is taken from the air, comes into the plant by means of the roots, but is found at maturity in leaves and stems.

Are such experiments conclusive?

No. They are more or less estimates. A pound of nitrogen in cow-pea vines may not be equal to a pound in manure; still, from our experience, we would as soon have the crop grown on the average acre as the 10 tons of manure.

But doesn't the cow pea demand the use of the land for a whole season?

Yes, in order to make seed, but a fair manurial crop can be grown after an early crop, and before frost.

Do you know that?

Yes, we have grown a fair crop of cow peas after early potatoes, also after picking strawberries. In the South cow peas are drilled in the corn after the last cultivation, or dropped in the hills when hoed.

Have others done it?

Yes; Prof. Cottrell, of the Kansas Agricultural College, tells of 15 acres of cow peas that were planted in Kansas on oat stubble. The planting was done July 16. The variety was Whippoorwill. By October 4 the vines covered the ground, and yielded more than one ton of hay per acre. One great virtue of the cow pea is that it makes a fair growth in a dry season. Most people are inclined to sow it too early. It is a bean, and will not stand frost or cold soil.

NOTES ON POTATO GROWING.

A POTATO ISLAND.—Victoria Island, about 20 miles west of Stockton, Cal., is said to contain the largest potato patch in the world. The land is "new," having been reclaimed from swamps. This year about 40,000 acres will be planted in potatoes.

The tracts are divided into districts, and small camps are established in each district. A white foreman is put in charge of several Chinamen, who are paid a certain sum for each acre they care for, and in this way the results are said to be far better than any other ever attempted. The payments for the work are made at intervals, and the services include planting, cultivating, digging and sacking the potatoes. When the tubers are ready for the market the final payments are made to the Chinese bosses, who distribute it among the laborers.

These potatoes are sent to San Francisco and shipped all over the Pacific country.

DIGGING IN SOUTH CAROLINA.—Our labor is very much opposed to potato diggers, thinking they are to take the place of the laborers in handling the potato crop. I can dig and sort, pick up and load into cars 1,000 to 1,500 barrels of potatoes per day by hand, digging with a potato fork, at about 12 cents per barrel. A man and two boys or girls will dig and sort 30 to 40 barrels of potatoes per day. We pay them 10 cents per barrel for digging, sorting and putting the potatoes into barrels. It costs about two cents per barrel to cover and haul the potatoes to the car, which is never over one-quarter of a mile from the potato field, as I haul spurs all through my fields. A man and two small boys or girls will earn $3 to $4 per day digging with forks, and they will not pick up the potatoes behind a potato digger. I have offered them 10 cents per barrel to pick up behind the digger; they say nothing, but simply walk out of field and leave mules and diggers alone. In the Fall I use the diggers all right, and gather my potatoes for about five cents per barrel, but cannot do it in the Spring when the whole country is planted in potatoes. W. C. G.

Youngs Island, S. C.

THE MATTITUCK CAULIFLOWER.—Fig. 124 shows heads of the Mattituck cauliflower grown by C. Weckesser, Wayne Co., O., who writes us that he grew about 2,200 of this sort, side by side with about 3,000 plants of Erfurt and Snowball. The Mattituck is exceptionally solid, single heads weighing 10 pounds, and it proved a favorite in the fancy trade, selling for a higher price than other varieties. The originator, Mr. March, has selected the strain of seed very carefully, and Mr. Weckesser says it gives uniform results which he has not heretofore obtained with American seed. Hereafter he thinks he may grow no other cauliflower unless it loses its present high qualities.

THE STRINGFELLOW METHOD.—I would say to those intending to experiment with root-pruned trees that it is not necessary to pound the ground except where it has been deeply plowed before. If already settled and firm, drive the holes about eight or 10 inches deep and use sand instead of soil to pour in with the water. Sand settles compactly, but I find that loam or soil will shrink. If such is used, then ram earth around the trees at the bottom, before watering. Fertilize well on top, mulch, or keep a three or four-foot circle clean, and this is all that is necessary. My trees, so planted a year ago, now have nice heads, and several peaches to the tree. I hope every reader of THE R. N.-Y. will risk at least one tree.

Texas. H. M. STRINGFELLOW.

The Cornell Reading Course.

Edited by John Craig, Professor of University Extension, and Editor Farmers' Reading Course, Cornell University, Ithaca, N. Y.

Orchard Management.

1. I have some apple trees that are full of blossoms every year, and set enough fruit, but keep falling the whole season until there is none to pick by the time they are ripe, which is August 25. I do not know the name of them. What is the matter? 2. Are Gano and Stayman good varieties of apples for this district? 3. What is the remedy for Woolly aphis? 4. I have been told that it is best to use lime on the ground where cow peas are to be plowed under, or they will sour the ground. Let me know how you handle them. 5. What kind of fertilizer would you advise using on a peach orchard, three and four years old? Would I receive any Benefit from wood ashes used this Spring in this year's crop? F. G. S.

New Hurley, N. Y.

As a rule the loss from dropping of early apples is much greater than that of Winter fruit. This loss may be traced to two principle causes: First, imperfect pollination; second, injury due to insects and fungi. Imperfect pollination means partial self-sterility. The blossoms are unable to fertilize themselves. This may be overcome by intermingling varieties which blossom at or about the same time. The second difficulty is overcome by spraying. No fruit grower or farmer with an orchard can afford to omit this necessary farm practice. In Bulletin No. 114, Cornell Experiment Station, directions are given for the preparation and application of sprays which destroy insect and vegetable parasites. 2. Gano and Stayman are two varieties of apples belonging to the Ben Davis type. They are favorites in the Southwest. I think they will give less satisfaction in New York than in the Mississippi Valley. They need a hot and dry season to give them quality. Scions may be secured of any of the western nurserymen. S. D. Lake, Shenandoah, Iowa, or C. L. Watrous, De Moines, Iowa, can no doubt supply you with scions or root-grafts of these apples. 3. Apple roots which are infested with Woolly aphis can be treated before planting by dipping the roots in kerosene emulsion. If they are discovered on the roots after the trees are planted the cheapest way to eradicate them is to dig the trees up and destroy them. The roots infested with Woolly aphis become knotty and gnarled, and the entire growth of the tree is stunted. The tendency is, of course, for the insects to spread from one tree to another. 4. There is no more reason for using lime on ground where cow peas are to be sown than in the case of any other crop. Lime is not a direct fertilizer. It is an amendment; that is to say, it tends to make available other elements of fertility in the soil. In this way it is valuable, but all soils do not need it. In some soils there is an abundance of lime present. There is also some danger of using too much lime on land, because the more plant food released, the more humus is used up, and if this practice is continued without adding humus to the soil by turning under green crops, the land may soon reach a worn-out condition. 5. One cannot answer a question of this kind satisfactory without knowing the character of the soil and the condition of the trees. If an orchard has been planted on a soil that has been cropped for a number of years, then on general principles I would use a nitrogenous fertilizer. If, on the other hand, the ground is in good heart, it is quite probable good results might be secured from the application of wood ashes. The best guide in this matter is the growth that the trees are making. If they are growing vigorously you will probably not make any mistake in applying wood ashes. If, on the other hand, the growth is not all that you might desire, then I would use some form of nitrogen, either barnyard manure, bone meal or nitrate of soda. The potash in wood ashes dissolves readily and should affect the growth of the trees the same season if applied in the Spring.

BEDBUGS AND THEIR KILLING.

It is doubtful whether there is any other insect inhabitant of temperate climates, so thoroughly hated by human beings as the bedbug. In the South there are many worse pests in the shape of bugs, ticks and spiders, some of them so small as to be invisible to the naked eye, but making a most distressing skin irritation. In large towns and cities bedbugs are a great nuisance, and, in houses where there are a number of people who go to work every day in different parts of the city, the housekeeper has to be constantly on the lookout for bugs. Many of the street cars are so infested that anyone who occupies a seat for only 15 minutes is liable to take home enough vermin on his clothes to stock the house. It is comparatively easy to keep country houses free from these pests, as there is not so much going and coming, and, if a house is once thoroughly freed from them it is easily kept so, something impossible in many city houses. Nearly all the drug stores sell preparations for making way with these insects, and there are various simple remedies, which are more or less effective. Benzine or turpentine will do the business, and may be put on furniture or cracks in the woodwork of a room without doing damage. Corrosive sublimate solution is not clean and rather unpleasant to use, but it leaves a coating of poison wherever it is put, which lasts for some time, and no bugs will come near it. For a building that is badly infested, however, there is probably no better remedy than a thorough fumigation with hydrocyanic acid gas. This is largely used in the fumigation of railroad cars, as it penetrates to every crack and does not injure furniture or hangings. This gas is formed by the union of cyanide of potassium with diluted sulphuric acid. It is a most deadly poison to everything that breathes, and must be used with the greatest care. Following are directions for fumigating a room with this gas: Find the cubic contents of the room by multiplying the height, width and length, in feet, together, divide this product by 200, and the result will be the number of ounces of cyanide of potassium needed. In the center of the room put an earthen jar containing twice as many ounces of water as the cyanide required. Add to the water 1½ time as much strong sulphuric acid (about 1.8 specific gravity), as the cyanide required. Stop up all the cracks in doors and windows to prevent the gas from escaping, throw open closets and toss up the bedding. Open doors and windows of the other rooms to allow a free circulation of air through the halls. Have the cyanide of potassium in a piece of paper; put it into the jar of acid and water; leave the room at once, and shut and lock the door. Be sure to *hold your breath* from the time the cyanide touches the liquid in the jar until you are out of the room, as the deadly gas is instantly generated, and one good whiff might be fatal. In about an hour and a half, open the room and air thoroughly. The gas will not injure carpets or curtains, but it is a good plan to set the jar containing the acid into a larger vessel, so that there will be no danger of the acid spattering on the carpet when the cyanide is put in.

Fruit Varieties for Maine.

J. S., N. Woodstock, Me.—1. What kind of apples would you advise me to plant in this latitude? Baldwins do well, while R. I. Greening is a total failure. Beauty of America does well. 2. Would peaches stand 20 degrees below zero on a dry hill farm? The land is good for corn and other hoed crops. If peaches would stand the climate, what kind would it be best to plant, and how should they be cultivated? 3. What kind of currants would you advise anyone to plant on dry upland, or would raspberries do better?

ANS.—1. North Woodstock is in one of the best apple-growing sections of Maine, and, unless for special local conditions on the farm in question, any of the standard varieties will do well. For market, plant few varieties. Baldwin is one of the best general-purpose apples for your section. Ben Davis is profitable, though of inferior quality. Tolman Sweet, Bellflower and Gravenstein may also be profitably grown. For home use add one or two trees each of Fameuse, Mother, and Winter Sweet Paradise, with Oldenburg and Munson Sweet for Summer and Autumn. 2. Peaches would be very uncertain in your section, though they are grown, to a limited extent, in York, Androscoggin and Cumberland counties. 3. The Fay currant is more largely planted than any other variety in Maine. It has the fault of breaking down badly in Winter, and should be protected from snow by tying a cord about the top of the bush in Autumn. Prince Albert is one of the most valuable sorts; a little later than most others, and retaining its foliage well. President Wilder is good, as is also Moore's Ruby. W. M. MUNSON.

Maine Exp. Station.

The Disk Harrow on Alfalfa.

I have about three acres of Alfalfa next to river bottom land. Will it do to cut it up with a disk, then sow more seed and harrow in? I also wish to add another strip, same kind of land, but at present it is in Timothy sod. Will it do to break this sod, harrow well, then sow to Alfalfa? At what time should such work be done? Anderson, Ind. G. M.

The Alfalfa root forms a crown above the surface of the ground. From this crown the stalks of Alfalfa grow, sometimes as many as 140 stalks growing from the crown of a single stalk, and often only five to 10 stalks growing from a crown. By disking the Alfalfa these crowns are cut and wounded, and new stalks thrown out. At the same time the disking makes a good earth mulch, and destroys weeds and grass. In our experiments we have disked Alfalfa two years from seeding and older. We have not tried to disk one-year-old seeding, as we were afraid disking might be too severe for the young roots. We issued a bulletin March 1 giving the results of our work. Since that date we have received several letters from Alfalfa growers who report that they have found it profitable to disk one-year-old Alfalfa. From the reports received it seems perfectly safe to disk year-old Alfalfa if care is taken to split the crowns, but not to sever the roots. We have tried sowing seed at the time of disking but without success. The seed germinates well, and while the old Alfalfa is small the little plants grow rapidly. After the old Alfalfa begins to shade the ground the little plants begin to die, and by the time the Alfalfa is cut the second time, all the young seeding has disappeared. A few farmers report success in thickening a poor stand of Alfalfa by sowing the seed at disking and then treating the old Alfalfa as though it were weeds—mowing it every 10 days until September. In this way the young Alfalfa gets a good start, and is not injured by shading. I should expect a failure from sowing Alfalfa on freshly-turned Timothy sod. If possible G. M. should raise a leguminous crop between the Timothy and the Alfalfa. Either Soy beans or cow peas are good. Alfalfa needs an easily available supply of nitrogen during the first six months of its growth. After that it will take care of itself. If it is not practicable to raise either of these crops then grow corn or some other crop that can be given clean culture. H. M. COTTRELL.

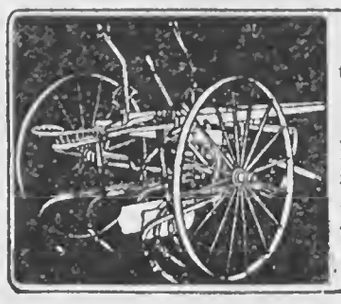
$5.00 Compressed Air Sprayer for $3.75

It is admitted by all classes of fruit growers and farmers that my 5 gallon compressed air sprayer is the most durable made. This reduction is made for a limited time only. Take advantage of the liberal offer—it may be your last opportunity to get the sprayer at the reduced price. $3 75 for galvanized steel, $5.00 for copper. **Will throw a good stream 25 to 30 feet.** Good pressure 20 to 30 minutes. **The tallest fruit tree can be sprayed.** Order to-day. Salary to reliable men. Address MARTIN WAHL, Rochester, N. Y.



DON'T HIRE A MAN to run this cultivator. Your little boy can do it just as well. That is because the **KRAUS Pivot Axle CULTIVATOR** is easier to operate than all others. A slight touch of the foot moves the entire machine to right or left instantly. Only successful cultivator for working hillside rows. Each gang has convenient lever for lifting and regulating. A center lever for spreading or closing gangs to suit wide or narrow rows Unusually strong and well made. Pin or spring hoe or spring tooth. Two, three or four shovels on each gang. We also make the Carpo Walking Cultivator. Write for free catalogue. The Akron Cultivator Co., Dept. D, Akron, O.

Ruralisms

NOTES FROM THE RURAL GROUNDS.

A FINE TOMATO.—We have just ripened a perfect specimen of the Ponderosa tomato, weighing a trifle over 14 ounces. It was quite smooth, colored to the stem, and contained less than 30 seeds, so that its solidity and high table quality are at once evident. This is, of course, not an unusual specimen as regards size, as Ponderosa tomatoes have been grown weighing three to four pounds under the most favorable garden conditions, but this one was produced on a cutting growing in a seven-inch pot. The Ponderosa does not usually produce enough pollen for self-fertilization under glass, and is not at all adapted for Winter forcing, though it is constantly growing in favor with amateurs who take pleasure in bringing it to perfection in their gardens by careful culture and training on a stake or other support. The large size and good quality of Ponderosa are very taking characteristics when it ripens thoroughly without the hard green core about the stem, which may result from unfavorable conditions. The particular fruit in question would be worth about 15 cents at this season in the local grocery, and it certainly required an expense in greenhouse space of several times that amount to produce it. The object in growing the Ponderosa was to secure a cross with other desirable varieties, which has been effected. Our plants of Combination x Best of All have been very productive, considering the harsh weather conditions, and bid fair to earn more than $1 per plant, based on local prices for Winter tomatoes. The Ponderosa plant shows an inclination to redeem its reputation by setting more fruits, which should ripen long before the garden tomatoes may be expected.

THE GREAT JAPANESE PARLOR FLOWER.—At this season, when the commuter's fancy lightly turns to thoughts of gardening the sidewalks of the various city streets leading to the Jersey and Long Island ferries are at times almost blocked with stacks of roses, shrubs, evergreens, fruit and ornamental trees, all with their roots tied up in moss and earth ready to be taken home and planted, as well as vast lots of Summer-blooming and left-over Fall bulbs. The dealers who offer these odds and ends of horticultural merchandise usually have a very casual idea of the proper names of the varieties, and some extraordinary and original labeling results therefrom. When one was asked the names of some dried-up Crocus corms he replied that he "didn't know just exactly, but he thought they were called Parotitis," which is a very good medical name for the disease commonly known as the mumps, but had never before been applied to the modest Crocus. A chronic offender is always offering bulbs of the "Great Japanese Parlor Flower." The attention of possible purchasers is assisted by a large and highly-colored painting, apparently representing a cross between a hollyhock and the brilliant South African orchid, Disa grandiflora. The bulbs offered by this ingenious fakir vary according to the season, from several species of Narcissus to lilies, Crinums, and occasionally the Elephant's Ear, Colocasia antiquorum. As most of the bulbs sold seem to be already dried up or dead, it is probable that flowers are not often produced to disappoint the buyers with their lack of resemblance to the painted representation.

MORE JERSEY ASPARAGUS.—That our Monmouth County asparagus growers are not discouraged by the fight with rust is evidenced by largely increased planting about Morrisville and Holmdel, not far from the Rural Grounds. These hamlets have long been noted for asparagus production, and the famed Conover Colossal variety first appeared in the vicinity. The Conover has been grown almost to the exclusion of other varieties until the advent of the rust, four years ago. Observation of different plantings, as well as information received from the State Experiment Station at New Brunswick, has convinced these practical men that the Palmetto and Argenteuil varieties resisted the rust much better, and they are now being planted locally to the exclusion of all other kinds except McDonald's Elmira, which is being cautiously tried by a single planter. Something more than 64 acres are now being planted with Palmetto and Argenteuil, preference being given to the first-named variety. These farmers say that more asparagus is being used than ever before. The crop is reasonably sure if the soil is congenial and the cultivation thorough. The profits are not great, but are less uncertain than in many other crops. These Jerseymen think by planting resisting varieties, shortening the cutting season, and keeping up high culture with thorough fertilization the ravages of rust may be greatly reduced. They don't take much stock in the practical economy of spraying for Asparagus rust, but may come to it in time.

ENDURING SPRING BULBS.—Quite a collection of hardy Spring-flowering bulbs was planted six years ago, tucking the groups away in odd corners, and the smaller varieties in little clumps under the grass of the lawn. No culture has since been given, and the only care taken at the time was to set each variety at the proper depth in fairly good soil. Most of the tulips and Narcissi remain to gladden us each Spring, though they have so increased that the foliage overshadows the blooms. The hyacinths have all disappeared except the Grape and Musk varieties, which hold on bravely. Among the minor species the snowdrops and Chionodoxas have alone survived. All the Crocuses, Irises and Scillas vanished after the second bloom. The Chionodoxas have sturdily increased, and quickly follow the snowdrop, opening before all the blooms of the latter have faded. They are very pretty with their intense blue flowers borne six to 10 on each spike. The bright color is relieved in some species by a conspicuous white center. C. Sardensis is all deep true blue. C. Luciliæ and C. gigantea both have the white eye, but the latter has the largest blooms of the genus. These charming little bulbs come from Asia Minor and the Island of Crete. They are now sold very cheaply under the popular name of Glory of the Snow. They hybridize at times with species of Scilla, but the hybrids are of little horticultural value.

Hope Farm Notes

HIDDEN TREASURE.—When we came to Hope Farm we found an old hogpen by the side of the old barn. It was about 10x20, with two ilttle houses in it. The floor was broken, and it had evidently been in service for years. There was a big crop of weeds growing shoulder-high in it. We have kept pigs there, though they were never comfortabie, but when the new hog-house was bullt we moved them all up to it, and pulled down the pen. We thought there might be two or three loads of manure, but a pick driven into the soil showed it rich and black, and we kept on digging and hauling until 11 good two-horse ioads had been hauled out. I would much rather have it than an equal number of loads of ordinary manure, as I think it is richer, and it certainiy spreads over the ground more evenly. I believe that fat iayer of soil and manure was worth $25 at least. It was mostly leachings through the broken floor, for we have cleaned the pen out several times.

LOST FERTILITY.—The remarkable mine underneath that hogpen makes me shut one eye and look at the two barns! When we came here we found stalls for 23 animals, and there were plenty of auger holes to let the liquids off easily. The barns are built on flat ground, and have no cellars. The soil beneath them must be as black as my hat, and as rich as a fertilizer factory. People in the South have told me how, during the Civil War, they leached compost heaps and the soii under them in order to obtain nitrate of potash for making gunpowder. Thus it was that the patient mules and motherly cows of the South provided some of the force that drove the builets and cannon balls home. There are nitrates enough under my barns to blow a big hole through the mortgage if I could only get them out and aim them properly. But, seriousiy—what an awful mistake we eastern farmers make when we let the manure leach down in this way, and then pay our good money for nitrates. Why, no nitrate of soda that ever was dug out of the South American desert into which Nature packed it can whip up crops any faster than the nitrates which have gathered under my barns. Yet, how are we to get at this wonderful store of fertility without tearing the barns down? One of them will need a new floor before long, and then we can tap that safety vault. The soil under that hogpen has made me love cement and hate an auger hole.

DRY UP!—I spoke last year of our damp cellar. It was a constant annoyance and we were always afraid of it. Every time the children had a cough or a cold the Madame would look at me and make an assault with the word cellar! The soil near the house is rocky and springy. Water seeps in from the sides and rises at the bottom. There were two large cisterns, which we have never used since our well was drilled. The formation of the ground made it impossible to put tiles under the cellar floor, as is often done. We dug a deep ditch from one side of the house, so as to give drainage from the cellar floor. A four-inch tile takes care of all the water that could come in. Then we put a thick coat of cement all over the cellar floor, grading it so that all water must run down to the opening in the tile. This has settled it. A little water works in at one side, but it cannot stay. The tile provides air drainage, and there is a current of air passing through which dries the cellar quickly. The stone cistern has been emptied, and I hope to have a hole broken through one wall so as to make a milk room out of it. It is a great satisfaction to be dry below stairs. The Madame can no longer remark "Damp cellar" when one of the Hope Farmers begins to feel his bones!

FARM NOTES.—The rain finaliy let up, and the sun and wind took the sap out of the soil so that we were able to plow for oats. It was raw weather, but Charlie tried to have the job well done. We formerly sowed grain and grass by hand, but this season we have a Cahoon broadcast seeder which does fine work. . . . . Nothing shows how "streaky" the farm is like the effect of a drying wind in early Spring. Here and there are fields or strips through the farm where the soil is ready to plow, while other fields or strips nearby are still soggy. Some fields receive the full force of our prevailing northwest winds, but I think the chief reason is that in places the rock comes quite close to the surface. There were some things about our potato field that I could not explain last year. I now see that in parts of the field the rock bulges up, so as to leave but little soil. When you come to understand a farm you can arrange crops and methods to far better advantage. . . . . I have mentioned a field at the far western end of the farm where we had cow peas last year. I had intended to put corn there, but finally changed to oats. It does not seem desirable to put a crop that one must cultivate or hoe so far away. It makes too long a journey in getting there. Some crop that will take care of itself is better. I want that field in Alfalfa some day. . . . . We have been planting some peach trees on the Stringfellow plan, or as near as we could get to it. I am frank to say that this kind of planting was done against the advice of every northern peach grower I consulted. Therefore, I am not going to say a word about it until it is too late in the season for setting others at it. I'll tell all about it later. . . . . A friend in Connecticut asks which he should sow for early hay—oats or Japan millet. "Oats every time!" would be my vote. We find oat hay very useful—but the seed oats must be treated in some way to destroy the smut germs. Japan millet, which I understand is the same as "Billion Dollar grass" makes a heavy growth on good moist soil. It is a useful green fodder, but hard and coarse for hay—in fact, it is not a good hay plant. I do not care for it, as I think the Thoroughbred flint corn grown in drills will make more and better fodder. . . . . In seeding the orchard we first plowed and then put the oats broadcast on the rough furrows. Then we harrowed both ways with the Acme. The Orchard-grass seed and clover were then put on and worked in with the Hallock weeder. It is often desirable to use the roller after grass seeding, but in this case the field was a little too damp, and I knew that the roller would pack it down too hard for the light seeds.

CLEAN GRASS.—What about our grass seeding after the Clark method? The lower field is a pretty sick-looking place. The grass started well, but the open Winter and the Spring floods have heaved and hauled and plowed and flooded it until it shows more of what Nature can do at its worst rather than what Mr. Clark could do at his best. On the higher parts of the field the grass is fine, but where the floods got at it there is little left. This failure is not the fault of Mr. Clark's system, nor is it entirely our fault. We might have ditched that field, or tiled it, yet we have had so much rain this Spring that more or less wash was unavoidable. Clark's method is all right if we understand that it means ideal conditions all around. We hear about big yields of potatoes or corn or fruit, but they are not obtained on ordinary soil or with ordinary care. That is also true of grass. If Mr. Clark's grass field had secured the flooding which Hope Farm has had this season he could show clean culture—that is, it would be mighty clean of grass. The grass field higher up on the hill looks better—in fact, it promises to give a good yield. I must state, however, that Charlie claims that the grass will still come up. He has more faith than I have.

WAXING FAT.—We have been interested in weighing the four baby Berkshires at intervals to see how fast they gain. Here are a few records: March 19, 14 pounds; April 1, 31 pounds; April 8, 45 pounds; April 15, 60½ pounds. One thing I am trying to get at is the amount of milk the old sow gives. She must be giving a good mess to provide this increase of young pork, for the little fellows have had nothing else thus far. I would like to know how this increase of weight compares with others. If there are others who have weighed young animals in this way I wish they would let us have the figures. Why do I want to know how much milk a sow gives? Am I going to boom the Hope Farm Berkshires as dairy animals? Well, not exactly, though good dairy qualities are desirable both in sows and ewes. I do a good many things that are more interesting than profitable at the moment, yet I find that most of them finally pay. H. W. C.

A FEW farmers of this locality will be short of hay this Spring, but those who have silos will have fodder enough. The corn crop was a remarkably good one, and all silos were filled. Many fields of fodder corn are in sight where no silos have been built by these farmers. More than a dozen will be built the coming Summer. With a silo filled with well-matured corn, so that but little heat and less acidity is developed, the farmer has a product which goes a long way towards reducing his feed bills, and helps materially in solving the problem of producing cheap milk. The corn fodder referred to has furnished a good shelter the past Winter for mice, and helped greatly in carrying the crows through the severe weather. It looks like a wicked waste of time and money for farmers to work hard all Summer that these pests may have a good shelter and enough to eat at his expense. Can any farmer afford to do business in this way?

AN ACRE OF CORN

and its possibilities under the Silage system—being the theme of

"A BOOK ON SILAGE"

By Prof. F. W. WOLL

of the University of Wisconsin. Revised and up-to-date, neatly bound into a volume of 234 pages. It embraces full information from planting to feeding the crop, and includes working plans and specifications for building all silos. Also embraces:

I—Silage Crops. II—Silos.
III—Silage. IV—Feeding of Silage.
V—Comparison of Silage and other Feeds.
VI—The Silo in Modern Agriculture,

And illustrations and complete plans for round and rectangular silos, dairy barns, tables of compounded rations, etc. **Mailed for 10c.** coin or stamps.

SILVER MFG. CO.
Salem, Ohio.

How to Drain Land Profitably.

On every farm there is probably some land that could be made more productive by underdrainage. Properly drained land can always be worked earlier, and more profitably. The best and most economical way to drain is explained in the book, "Benefits of Drainage and How to Drain," which is sent *free* by

ROUND TILE

JOHN H. JACKSON, Third Ave., Albany, N. Y.

WHY

Can we Save You Money on a vehicle, harness or a fly net?

Because we have no agents.

Can we really do it? We say yes. Can we prove it without cost to you? We can. How? We will ship you a harness, saddle or vehicle, without you sending a single cent, and let you look it over at your freight house and if you don't find we have given you the biggest bargain you ever saw or heard of, return the goods to us at our expense. We give with each vehicle a 2-year iron-clad guarantee, protecting you from poor material and workmanship. Our vehicle catalogue describes the largest line of buggies, road wagons, phaetons, surries, spring wagons and carts, harness and fly nets ever shown in one book. It's free. Send for it.

Marvin Smith Co. 55-59 N. Jefferson St. U-2 Chicago, Ill.

BUGGIES AND HARNESS

HARNESS $4.15

THIS $50 TOP BUGGY $28.50

YOU CAN BUY FROM US AT FACTORY PRICES

Buggies-Phaetons-Surreys-Wagons-All kinds of Harness

We will sell direct to you a vehicle or harness as cheap as dealers buy their goods in car-load lots. Don't pay profits to middlemen. Our work is all high-grade, correct style, and elegantly finished.

Send for **FREE CATALOGUE** Showing Largest Line Vehicles and Harness in the United States.

All work Guaranteed and Shipped on Approval

CONSUMERS CARRIAGE & MFG. CO.

232 So. Desplaines street, CHICAGO, ILL.

This Company is reliable.—Editor.

SPLIT HICKORY

You know what Split Hickory is? It's the best possible material for vehicle building. It is what makes

The Famous **Split Hickory Vehicles**

the leaders in the trade. They are right in every detail. They have scores of "little things" which add to their durability, their comfort and their beauty. We sell them to you direct from the factory, saving you all jobber's and agent's commissions.

We Ship on Approval

to anyone anywhere, and guarantee perfect satisfaction. Our free book tells lots of things you ought to know about vehicles. Send for a copy.

OHIO CARRIAGE MFG. COMPANY,
39 W. Broad St., Columbus, O.

No. 232—Driving Wagon. Has "Long Distance" axles, open head springs, Bailey loops, rubber covered steps and solid rubber tire. Price with shafts, $65. Same as others sell for $40 to $50 more than our price.

You Pay Double the Money

in many cases when you buy vehicles and harness from the agent or dealer. We do without these people and reduce the price of our goods to you to the extent of their commissions. We make 178 styles of vehicles and 65 styles of harness and sell them to the consumer direct from our factory at wholesale prices.

WE HAVE NO AGENTS

You pay a profit to nobody except our manufacturing profit, and you get the best goods which a given amount of money will buy. In a factory of the size of ours you get the **best possible selection.** Our large illustrated Catalogue contains cuts of everything we make. Remember that we ship our vehicles and harness anywhere for examination and guarantee safe delivery and warrant everything

No. 65—Single Buggy Harness. Price with rubber trimmings $16. Good as retails for $22.

The Rural New-Yorker

THE BUSINESS FARMER'S PAPER.

A National Weekly Journal for Country and Suburban Homes.

Established 1850.

HERBERT W. COLLINGWOOD, Editor.
DR. WALTER VAN FLEET, H. E. VAN DEMAN, MRS. E. T. ROYLE, } Associates.
JOHN J. DILLON, Business Manager.

SUBSCRIPTION: ONE DOLLAR A YEAR.

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs.

"A SQUARE DEAL."

We believe that every advertisement in this paper is backed by a responsible person. But to make doubly sure we will make good any loss to paid subscribers sustained by trusting any deliberate swindler advertising in our columns, and any such swindler will be publicly exposed. We protect subscribers against rogues, but we do not guarantee to adjust trifling differences between subscribers and honest, responsible advertisers. Neither will we be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent us within one month of the time of the transaction, and you must have mentioned THE RURAL NEW-YORKER when writing the advertiser.

Name and address of sender, and what the remittance is for, should appear in every letter.
Remittances may be made in money order, express order, personal check or bank draft.

THE RURAL NEW-YORKER,
409 Pearl Street, New York.

SATURDAY, APRIL 27, 1901.

WE understand that Congressman Tawney, of Minnesota, will introduce the anti-oleo bill as soon as Congress meets, so it will be the "Tawney bill" this time. That's a good name for it. Webster defines "tawny" as matter that looks as if it had been tanned. That will describe the appearance of the oleo people when that bill runs over them. Mr. Tawney has been an active champion for honest butter.

*

Now the Secretary of Agriculture is preparing for a free tree distribution, in addition to his free Government seeds, and perhaps, in the course of time, we may see a free distribution of hammocks, garden settees, spike-tooth harrows, spraying outfits and grafting wax. Or perhaps Uncle Sam may further gladden us with a free distribution of outing hats, bicycle tires and tennis rackets. Why not?

*

READERS will remember that last Winter H. M. Stringfellow, of Texas, issued a challenge to peach growers who would plant trees according to his system of close root-pruning. Two Maryland growers have accepted the offer. One is in the mountains and the other on the lower level lands of Kent County. The trees have been planted. The Hope Farm man has also planted several hundred trees in this way. We hope to give regular reports from these experiments.

*

THE Jewish agricultural school at Woodbine, N. J., has set an example in business which other schools might copy. This school seeks to fit boys for a job and then fit them into one. They advertised, and as a result we understand that every boy who was ready found a good place. Some of the agricultural colleges are trying this method; it would pay them all to try something of the sort. The teachers in the Jewish school go further. They start their graduates with a year's subscription to THE R. N.-Y.—often paying for it out of their own pocket. That is what you might call giving a boy a liberal education in agriculture and then nailing it in.

*

THE American Grocer gives the following estimate of the value of some of the beverages consumed by the people of this country in the year 1900:

Alcoholic drinks	$1,059,563,787
Coffee	125,798,530
Tea	37,312,608
Cocoa	6,000,000
Total	$1,228,674,925

Probably the amount expended for "soda water" would bring this total nearly to one billion and a half of dollars. A few other figures taken in connection with this drink bill are interesting. The total value of all paper money in this country March 1 was $1,455,188,260. On July 1, 1900, our total interest-bearing public debt was $1,023,478,860. One year's consumption of alcoholic drinks would pay every dollar and square up last year's interest charge of $33,545,130. Here are the total values of certain farm crops:

Total value of cotton crops	$334,847,868
" " Potato crops	90,811,167
" " Wheat crops	323,525,177
" " Oat crops	208,669,233
" " Barley crops	24,075,271

A farmer, while following the plow, has much time for reflection. We have often wondered what the plowman has in mind. It might not be a bad plan for him to turn this thought over in his mind as he watches the furrows fall: "The money spent for liquor last year in this country did no one any real good. It would have paid our National debt. All the five crops named above could have been purchased with it, and there would have been enough left to buy all the sheep in the country; at the same time there were thousands of people living on charity and thousands more without food or clothing."

*

AT the last session Congress gave the National Agricultural Department authority to inspect butter for export. When such butter is found up to the required standard the Department inspectors may certify, grade and label it. This authority will go into effect July 1. The Department regulations have not yet been formulated, but efforts will be made to promote the export of the kind of butter which foreigners desire. Of course any butter may be exported whether inspected or not, but naturally the butter guaranteed by the Department would have the preference. For some years now the Department has been studying the foreign butter markets. The idea of this new plan is to give the foreign trade a chance to buy certified products if they desire to do so.

*

WE have read newspaper statements about the dog tax law of Westmoreland County, Va. One report stated that the tax was so large that the dogs would soon pay for the new county buildings. The fact is that this tax (50 cents and $1) brings in about $800 per year. Thus far it has been largely evaded. When heads of families are asked whether they own the several dogs known to lodge at their home they often claim that the curs are owned by members of the family whose names are not on the assessor's list! Hereafter all dogs on the premises will be assessed as the property of the head of the family. This will add at least one-third more to the income from this tax. The object of the tax was not revenue so much as a desire to get rid of as many sheep-killing curs as possible. Still, if the curs can bark out $1,000 revenue so much the better!

*

THE New York Legislature has finally killed the proposition to spend $26,000,000 for improving the Erie Canal. Two classes of citizens combined to defeat this measure—the farmers, who do not want any money spent on the canal, and city people who want a great deal more than the bill called for. The State Grange and other agricultural organizations took strong grounds against any appropriation. The farmers can see no benefit to agriculture from any canal, for it will simply aid in bringing western food products into the territory properly fed from their own farms. The New York City commercial associations want a great barge canal, which would cost the people of the State $100,000,000, more or less. It seems like an outrage to saddle this tremendous expense upon the State when the benefit if any would go to New York City and the western shippers. If such a canal is built it should be a National ditch—the expense borne by the entire country.

*

THE Governor of New York has signed the bill providing that milk cans stamped with the name of the owner must not be used by others without the owner's consent. Another good move is now in order, namely, a law to compel receivers of milk in this market to turn a jet of live steam into every can before it is returned to the farmer. This would be no special hardship, for connection with live steam may be had without great cost at most of the receiving stations. If the cans are allowed to stand several days unwashed the milk dries and they never get thoroughly cleaned. Live steam is the stuff for this business. Some of these cans are sent back in a horribly filthy condition. We have seen them partly full of swill and garbage from restaurants. The law forbids the selling of skimmed or separated milk in this city, even for what it is, and hundreds of people are thus deprived of a cheap and wholesome Summer food, yet there is no law to keep the dirty old milk can from traveling back and forth, peddling and mixing with the milk cartloads of filth and germs.

*

A LAW in Minnesota prohibits pool-selling and book-making on the fair grounds. For six years this law has been enforced, with the result that the State Fair has been a great success. The friends of the gamblers and the "tough" element have tried again and again to have this law changed. This year they waited until six days before the end of the session, and then put in an amendment. They called it "An act to encourage horse breeding," but it would probably have killed the original law. They thought it was too late to bring farmers and their friends together, but they forgot the rural telephone. As soon as the nature of that bill was known the telephone wires began to hum! By the time the Senate committee got together for a hearing their room was crowded with people who had come to protest against that bill. They had talkers with them, too, and when a few of them finished the pool sellers never said a word and the bill was killed by a unanimous vote. That was a glorious day for the telephone and the tongue. Whenever the farmers of this country will get together and talk up fairly and fearlessly they will defend their rights successfully.

*

A CITIZEN of Minnesota, Samuel Haugdahl, won great fame at Paris as a butter maker. His tub of creamery butter traveled all the way from Minnesota, stood up against the work of the best butter makers of Europe, and bowled them all over—winning the grand prize. In referring to this the Minneapolis Journal well says:

> If the victories of peace are no less than those of war, Kansas may have her Funston, Georgia her Hobson and Iowa her Calvin Titus. Minnesota is quite content with her matchless butter maker.

Unfortunately the "victories of peace" are not so popular as those of war. In our opinion the man who writes his country's history in butter is far more deserving of applause than he who smears it in blood. Yet, the white apron of the butter maker must take a back seat for the soldier's blue uniform! Which, say you, was more productive of good to the plain farmers of this country—the capture of that Paris dairy prize or the capture of Aguinaldo?

*

AMONG the many bad bills proposed by the present New York Legislature few were more worthy of unqualified condemnation than the so-called Stranahan mortgage tax bill. This measure proposed to levy a nominal tax on mortgages for State purposes and to exempt them from local or municipal taxation altogether. It also proposed to exempt from taxation altogether mortgages held by insurance companies, title guarantee companies, savings banks and similar institutions. By the first condition this gives mortgages a preference in the matter of taxation, above all other kinds of property, and by the second claim gave insurance companies, banks and trust companies a virtual monopoly of real-estate mortgage investments. These favored monetary institutions operate for the most part in cities. On the other hand, farm mortgages are mostly held by individuals who would be taxed, and they would find in this an excuse for advancing the rate to the legal limitation. The city owner would probably be able to borrow, at as low a rate, as before, from the favored institutions by bearing the entire burden of local taxation, while the holder of his mortgage escaped the tax collector entirely. The farmer, however, would bear the burden of local taxation just the same, and would suffer besides an advance of interest rate.

*

BREVITIES.

Hans brought his fortune on his back,
Down at the bottom of his pack,
Wrapped in a bag beside his shirt,
He kept two quarts of German dirt,
Brought from his own loved Fatherland;
And with his hard and clumsy hand
A rose he planted in it—then
He said, the happiest of men,
"I pring dot soil mit Chermanie
To dake me pack mit memory.
Dot rose from Cherman soil he grow
Der true Amerigan—dot's so!"
So may the swarming hordes that come
From Fatherland to find a home,
Root like the rose in memory
Of all things good across the sea,
Yet grow to noblest type of man
Worthy the name—American!

THE robber cow can't fill the can.

DON'T think that the letter *I* is the "key note."

A COWARD can turn even a bubble into a trouble.

MR. Hoyt and Mr. Bassett discuss the spraying problem.

THROW light into dark places—especially when seed potatoes are there.

THERE has been much complaint about adulterated clover seed this year.

THE California fruits have ruined the market for evaporated raspberries.

A GOOD sign—most of the experiment stations are issuing bulletins on Summer forage crops.

THE hen puts all her eggs in one basket—but then the hen knows more about eggs than you do!

"THERE is that scattered that increaseth!" For instance, your own strength when you give it to others.

TOTAL money cost of the war in the Philippines to date about $280,000,000. Total cost to England of the Boer war $725,000,000!

WANTED! Information from those who have used a spray pump for putting on whitewash or paint. What nozzle? How thick is the wash made?

REPORTS accumulate of hens that make a good living on cow peas! We have made some claims for cow peas in our day, but for us they have not laid eggs.

WE feel sure that we can raise crops for less money by putting the manure over more ground and piecing out with potash and phosphoric acid in chemicals.

THE recent article on Pear blight by D. R. Pease has called out many questions about the use of lime and sulphur. Another article next week will answer them.

Events of the Week

DOMESTIC.—The United States transport Rawlins took fire at her dock in Brooklyn, N. Y., April 10. She was pumped full of water and sunk, with a total damage, including cost of raising her, of $70,000. . . . . Woman suffrage was again defeated in the Wisconsin Assembly April 9, the Evans constitutional amendment permitting women to vote being killed by a vote of 61 to 30. A similar amendment has already been killed by the State Senate. . . . . Governor Hunt has issued a proclamation abolishing martial law in Shoshone County, Idaho, which was established at the time of the riots of two years ago. . . . . An avalanche near Adelaide, Col., April 12, buried a work train, killing three men and seriously injuring four others. . . . . April 12, the weather cleared at Denver, Col., after a snowstorm of 96 continuous hours, being the heaviest April snowstorm for many years. . . . . George Q. Cannon, leader of the Mormon church, died in California, April 12, aged 74. One of the first emigrants to Salt Lake, he soon acquired the position of a leader among the Mormons. In 1865 and the five succeeding years he was elected to the Legislative Council of Utah, being at the same time a Regent of the Deseret University. He was a member of the State Constitutional Convention of 1872, and was elected a delegate to present the Constitution and a memorial to Congress for the admission of the Territory into the Union as a State. He was elected delegate to several Congresses, beginning with the Forty-third, but he had to leave the Forty-seventh because he admitted that he was living with four wives. His second wife was the daughter of Brigham Young. . . . . The Federal court at New Orleans has decided that the shipment of mules to the British in South Africa cannot be stopped by injunction, the court having no jurisdiction. . . . . A student at the University of Michigan, Ann Arbor, contracted bubonic plague from an accident with plague bacilli in the laboratory. He will recover, and there is no fear of further spread of the disease. . . . . It is said that gold has been discovered in paying quantities along the Kaskaskia River at Pana, Ill., assaying $4 to $12 a ton. . . . . Phineas M. Blodgett, whose father was a member of Washington's army, died April 16 in Chicago. He was born in Groton, N. Y., in 1809, and had voted for 18 Presidents. . . . . An express train ran into a wagonload of Indians April 16 at a crossing near Blue Jacket Station, Indian Territory, killing two men and seriously injuring a woman and child. . . . . A head-end collision at Woodbine, Iowa, April 16, between two Illinois Central passenger trains, resulted in the death of one man, probably fatal injury of another and the serious injury of several passengers. . . . . Four persons were killed and seven injured April 17 by an explosion on a steamer near Vancouver, B. C.

PHILIPPINES.—The chief of staff of the insurgent, General Mascardo, has surrendered at the town of Marivales, in Bataan Province, Luzon. He said that Mascardo's band of followers, now greatly diminished, are in a bad way. It is impossible for them to elude the Americans; they are unable to obtain food, and want to surrender. It is expected that General Mascardo himself will surrender shortly. A court-martial has been convened at Manila, and met April 18 to investigate the commissary frauds. A number of army officers and civilians are implicated.

ADMINISTRATION.—There is no present prospect that a new isthmian canal treaty will be negotiated with Great Britain before Congress meets, for the reason that Senators continue to tell Secretary Hay that no treaty different from the amended one which Great Britain rejected could be ratified by the Senate.

GENERAL FOREIGN NEWS.—The Republic of Mexico signed the convention of the Peace Conference at The Hague April 17. China, Luxembourg and Turkey are now the only countries which have not signed. . . . . A South African Blue Book has been issued by the British government reviewing the situation in the Boer war as presented by Sir Alfred Milner. While assured of ultimate success, he says the work will be slow and costly, and he admits that during the last six months there has been retrogression in the campaign.

FARM AND GARDEN.—Chicago packing houses have been advised by their agents in London that the British government has excluded all beef except home-bred from army contracts. The Agricultural Department at Washington has been notified. The value of our exports of live animals to Great Britain amounts to $40,000,000, while the total of animal products exported from the United States to Great Britain is stated to be, in round numbers, $200,000,000. It is believed that this proposed embargo may really be a sequel, in greater or less degree, to the proceedings instituted at New Orleans against shipments of horses and mules from that port for use in the South African campaign. It is pointed out that if the English really decided to take the action reported, the British might turn to Australia for their meats. It is claimed, however, that meats cannot be got there in as good a quality or as cheap as in the United States.

Frank D. Gardner, of Illinois, an expert in the Soils Division of the Department of Agriculture, has been appointed to take charge of the experiment station work in Porto Rico.

American corn is now the object of attack of the French agrarians. United States Consul Thackera, at Havre, makes this subject the basis of a considerable report to the State Department. He says, in brief, that the French agrarians and some other interests became alarmed some time ago at the increasing use of foreign corn, and have succeeded in having two bills reported for passage, the first regulating the temporary admission of corn, and the second fixing the duty on grain at 96 cents instead of 58 cents per 100 kilogrammes, and increasing the duty on flour made from corn from five francs to eight francs per 100 kilogrammes.

The combination sale of "all Scotch" Short-horn cattle was concluded April 6 at the Chicago stock yards, 46 animals being sold for an average of $719 each. Thirty-seven cows were sold for an average of $710 each, and nine bulls sold for an average of $754 each. The highest-priced cow was "Victoria of Hill Farm Sixth," sold for $2,100, to Frank Bellows, of Maryville, Mo., and the highest-priced bull was imported "Fearless Archer," sold for $1,650 to Alexander Bruce, Buenos Ayres, South America.

A notable sale of pine trees has been made at Scio, Allegany County, N. Y. Lucius and Ebenezer Norton, owners of 490 trees which are the remnant of the original forest on the Allegany hills, sold them for $7,500. The trees are to be hauled to Wellsville and Belmont, and it is expected that 720,000 feet of lumber will be obtained from them. The price paid probably was the highest ever secured for pine on the stump, the average price per tree being $15. Pine lumber is worth $70 per 1,000 feet. These trees are the last clump of virgin pine in Allegany County, the other trees having been bought in the past three years owing to the increase in the price of lumber. The largest pine cut thus far measured 16 feet in circumference at the butt, and the rings indicated that it was more than 295 years old. There is now little standing timber in the county, the telegraph companies and railroads having used most of it for poles and railroad ties.

The directors of the Wholesale Seedsmen's League, representing all the great seed houses in the United States, met at the Astor House, New York City, April 11, and adopted a resolution declaring that the Secretary of Agriculture of the United States, through the manner in which he is allowing the contract to be filled for seeds for free distribution this year, has brought the seed division of his department into disrepute and departed from all precedents in any department.

The firm of Segarl, Stich & Meyer, of New Orleans, received two barrels of new potatoes April 3 from the "Home Place" on the Louisiana lower coast. They were the first arrivals this season, and of course brought a fancy price. But in this case the sale was made at $14 per barrel, which smacks much more of Boston or New York values than any former New Orleans price.

Reports have been sent to the Middle West to the effect that the Secretary of the Interior is the Government official who is dispensing vaccine for protection of cattle against black-leg. The Secretary has been obliged to direct scores of those who inquire about the matter to the Department of Agriculture. He suggests that matters would be greatly facilitated if those who want the vaccine will address that department direct, as his department has nothing to do with the doctoring of cattle.

Peoria, Ill., purposes to hold, in 1902, an exposition which shall represent the labors of the corn-growers throughout the great Western corn belt. Next year is considered an off year in big expositions, and the movement now under way gives promise of success. The proposed exposition finds an enthusiastic promoter in E. S. Fursman, president of the Illinois Corn Growers' Association, who has been in charge of the exhibition for three years, and who is to superintend Illinois' corn exhibit at the Pan-American Exposition this year. The plan for the proposed corn-belt exposition includes the organization of a strong stock company to stand behind the enterprise.

The farmers of the Kansas wheat belt will organize on May 16 at Salina, and arrange for independent shipment of wheat to market. They favor direct shipment to Liverpool by many of Gulf ports, avoiding eastern markets.

The annual meeting of the American Guernsey Cattle Club will be held at Fifth Avenue Hotel, New York City, May 15, 1901, at 10:30 A. M. Besides the usual routine business, there will be some matters of great interest considered. The results of the home butter contest, ending May 1, will be announced, and the establishment of an advanced register for Guernseys will be discussed.

The New York State Fair Commission met at Albany, April 17, and elected the following officers: President, Lieut.-Gov. Woodruff; vice-president, Charles A. Wieting, State Commissioner of Agriculture; secretary, S. C. Shaver, Cobleskill; treasurer, A. R. Brown, Batavia; superintendent of grounds, H. A. Moyer, Syracuse; superintendent of races, Theodore Coleman, Hornellsville; superintendent of horse show, Ralph Hyde, New York. The commission meets in Syracuse, May 2.

HOW AND WHEN THEY SPRAY.

What New York Fruit Growers Report.

The following reports from members of the New York Fruit Growers' Association give a fair idea of the practice of spraying:

About all fruit growers here spray the last week in March to middle of April; spray for leaf curl on peach trees. No power sprayers used in this section.
Ulster Co. J. A. H.

I do not know of an orchardist who does not spray, and the power pumps are used to some extent, but not more than one in a hundred. I do not believe they are profitable in our ordinary-sized orchards. S. W. W.
Monroe Co.

I do not care to spray until the blossoms fall. Most of the fruit growers through this section spray, but no steam or gasoline engines are used for that purpose, so far as I know. A. D. C.
Orleans Co.

Probably three-fourths of our fruit growers spray their trees at present, both peach and apple trees. There are only two power sprayers in our vicinity. Most of the people use hand pumps, as they think they are the most economical. C. J. M.
Niagara Co.

About 90 per cent of the fruit growers spray, commencing just before the bud opens for blossoming. There are only a few steam or gasoline sprayers in this section, but more are coming into use every year. They seem to be expensive for the farmer with a small orchard.
Orleans Co. C. S. W.

I think nine-tenths of the growers spray. There is no spraying done by steam in this section. I know of but four that are worked by power, and they are attached to the wheel of the wagon. I spray the first time just as the apple buds separate; I mean by this when the leaves unfold. The blossom bud is like a round ball, and in a day or two they separate so one can get the spray in and all around the buds. I treat my pears and plums in the same way. E. A. C.
Niagara Co.

At least nine-tenths of the fruit growers in this county spray, and all by hand power. The first spraying is done immediately before the buds begin to swell, which last season was April 25, the day I commenced spraying the first time. I should not consider power spraying profitable only in very large orchards. C. W. O.
Niagara Co.

Nearly all growers spray. None use power pumps. The large double-action hand pump is used in nearly all cases. We spray with Bordeaux Mixture as soon as the ground will bear up the team and wagon. I used arsenite of soda last season, and would not think of going back to Paris-green. It is much more effective; does not precipitate; more convenient and cheaper. C. R. W.
Ontario Co.

Half the orchards (barring a few old abandoned ones) are sprayed, but very few are done thoroughly. I expect to spray apples just before the buds open. There are no power sprayers in this neighborhood, but I consider it the best way to use power pump or steam pump on account of the fineness of spray and thoroughness with which it can be done. J. Q. W.
Ontario Co.

Spraying for leaf-eaters and the Codling moth is practiced by possibly 10 per cent of our farmers, and by all of our fruit specialists. Spraying for blights is confined to a few vineyardists, who make about three applications of Bordeaux, the first one soon after tying up. Apple scab was very prevalent for many years, but is little seen recently. I think there are no engine-power sprayers in this county, though our largest vineyardists are considering the advisability of better equipment. A public sprayer would find large patronage. J. T. R.
Onondaga Co.

From 50 to 75 per cent of our fruit growers spray in this section, but only a small percentage spray thoroughly and with Bordeaux. We like to spray for the first time just as early as the ground is in shape to drive over; the second time just before the blossom opens. There are no steam or gasoline engines used for the purpose of spraying in this section; the best apparatus for the purpose in this locality consists of a tank holding about 300 gallons, surmounted by a staging six feet above tank for the men holding and directing the nozzles to stand upon. The man who drives does the pumping, using a good pump (Eclipse or Pomona) with two lines of hose 25 feet each in length. A. H. McM.
Wayne Co.

I think about two-thirds of apple growers sprayed their orchards last year. A good many new spray tanks are going out this Spring, which makes me think that more people are preparing for spraying this year. Most apple growers spray before buds open; then just as soon as blossoms fall; then again about 10 or 12 days after second spraying. I never have heard of any spray rigs run by gasoline; knew of one man who had an oil burner to run his spray rig, but did not like it, and substituted a coal burner. I know of three coal burners, 1½ horsepower, running last year. If ground is soft it needs three horses to draw spray rig; tanks holding 250 gallons are pretty generally used for large orchards. I hear of four new coal burner sprayers having been ordered for this Spring's use. F. G.
Orleans Co.

THE VALUE OF QUOTATIONS.

Considerable has been said on this subject of market prices quoted for country produce, yet it does not seem to be generally understood. The only way to get an absolutely correct report would be to see all dealers in a certain market every day and get a full account of sales and prices. No commercial daily, however, claims to do this. It might be done in a small town, but in a large market like New York or Philadelphia, the undertaking would be enormous, and the space required to print all the facts greater than any market paper could give. Of course, the prices of grain, butter and eggs are made daily on the produce and mercantile exchanges, and wholesalers throughout the city take these figures as a basis for the day's business. They may now and then get a higher price for a certain grade from a customer who needs it badly, or they may have to cut in order to make a sale, but this exchange price is taken as a sort of par value for the day. On other products, such as fruits, vegetables, etc., the usual plan in quoting is to give a range of prices covering both high and low. There are extreme prices, however, on both ends that it is not thought wise to give, as they are more likely to mislead than help. A reader says that for a certain grade of sweet potatoes his neighbor has been getting 25 cents per barrel more than the market prices quoted. However, sales as a rule would not warrant quoting such a figure. This man evidently had better potatoes than most of that grade. His agent in this city saw that they were worth more, and held them for the higher price. Some men in preparing a certain grade of produce for market make it as poor as they can without being put in a lower class, while others make it really better than is necessary, and frequently get no returns for their extra trouble. Where the selling agent takes an interest in the matter, and is willing to do a little extra work to get what the stuff is really worth, the careful and honest packer usually gets pay for his extra trouble. Another man may send stuff which is graded in the same class, yet at the foot of the class, and on this account fail to get the premium his neighbor did. Of course, all produce ought to be sold on its merit, or lack of merit, but in order to quote it, there must be some grading, and where such a wide range of quality is allowed in one grade, such a grade cannot be connected with anything definite in the way of prices. No one claims that this is as it ought to be, but an effort is made to give a fair range of prices, and the matter should be studied from all sides by shippers. W. W. H.

Woman and Home

From Day to Day.

HEAVEN'S DISTANT LAMPS.

We see but dimly through the mists and vapors,
Amid these earthly damps;
What seem to us but dim, funeral tapers,
May be Heaven's distant lamps.

There is no death! What seems so is transition;
This life of mortal breath
Is but a suburb of the life elysian,
Whose portal we call death.

She is not dead—the child of our affection—
But gone unto that school
Where she no longer needs our poor protection,
And Christ himself doth rule.

In that great cloister's stillness and seclusion,
By guardian angels led,
Safe from temptation, safe from sin's pollution
She lives, whom we call dead.

Day after day we think what she is doing
In those bright realms of air;
Year after year, her tender steps pursuing,
Behold her grown more fair.

Thus do we talk with her, and keep unbroken
The bond which nature gives,
Thinking that our remembrance, though unspoken,
May reach her where she lives.

Not as a child shall we again behold her,
For when with rapture wild
In our embraces we again enfold her,
She will not be a child.

But a fair maiden in her Father's mansion,
Clothed with celestial grace,
And beautiful with all the soul's expansion
Shall we behold her face.

—Longfellow.

*

A good many industrial facts imparted by the geographies puzzle the young mind, and we can all sympathize with the small girl who read in her lesson that "Yarmouth is celebrated for the curing of herrings." "Oh, how funny it must be," she exclaimed, "to see the little sick herrings sitting around getting better!"

*

What is said to be the first laundry school ever established has been fitted up by the League for Social Service in New York City. The women employed are required to take a course of training in different branches of the work, being paid while learning. The idea of the League is to provide a place where women may secure training that will enable them to procure self-sustaining employment. In all cities there appears to be a scarcity of competent laundresses, especially of those able to do fine ironing or to wash flannels, and training in such lines is much needed.

*

One of the newest Spring styles in neckwear is a tie of grass linen in its natural ecru shade, having a narrow hemstitched border of contrasting color. The tie is three or four inches wide and a yard long; it is put around the neck once and tied in a little bow, or arranged like an Ascot. Batiste sailor collars or revers seem to be as popular with Spring jackets as last year, some being simply hemstitched and tucked, others inset with lace or embroidery. They are a handsome addition to an Eton jacket, and are especially used on the little silk Etons so fashionable.

*

An Alsatian proverb says that, to make a durable pair of shoes one should use for their sole the tongue of a woman, since it is the one substance that never wears out. There is nothing new under the sun, and such gibes at feminine loquacity were old when Solomon added his testimony to them. Most of us have more reason to watch the quality than the quantity of what we say. It is the woman who talks perpetually of trivial and uninteresting matters of whom the sage spoke when he said: "As climbing a sandy way to the feet of the aged, so is a wife full of words to a quiet man."

The Rural Patterns.

Box-pleated frocks for little girls are both fashionable and becoming, and the model illustrated shows the popular long French waist. The original is made of linen duck in pale blue and is trimmed with white needlework edging and insertion, but piqué, lightweight linen, madras and all similar washable fabrics are eminently appropriate, while

3780 Girl's Box Plaited Dress, 4 to 12 years.

cashmeres, henriettas and the like make most admirable materials for cooler weather wear. The fronts and back are lad in two straight box-pleats that extend from the shoulders to the edge of the skirt, being stitched on their underfolds to the belt line and falling free below. The stylish adjustment is accomplished by shoulder and under-arm seams only, slight fullness being gathered under the belt and stitched to position. The fronts are cut away at the top and closed in double-breasted style, the closing below the belt being invisibly accomplished, that above by means of pearl buttons and buttonholes. At the neck is a big sailor collar, beneath which the shield of embroidery is attached. The sleeves are in bishop style with narrow cuffs, which match the standing collar. At the waist is a belt that passes through straps at the underarm seams which serve to hold it in place. To cut this gown for a girl of eight years of age four yards of material 32 inches wide or 3⅜ yards 44 inches wide will be required. The pattern No. 3780 is cut in sizes for girls 4, 6, 8, 10 and 12 years of age; price 10 cents from this office.

The shirt waist shown is a popular model in the new Summer garments. The smart model shown is made of white lawn with revers of all-over tucking, while shield, collar and cuffs are of fine embroidery; but the same design is available for silk and woolen materials and for all the range of cotton and linen stuffs. In the new shirt waist flannels woven with silk stripes it is admirable combined with taffeta; made from albatross it is eminently satisfactory and when unlined and made from batiste, madras, Swiss muslin, dimity and the like, it is an ideal Summer bodice. The foundation lining (which in this instance is omitted) closes at the center front. On it are arranged the back, the full fronts and the shield—this last being attached at the right side and hooked into place at the left, while the waist closes at the center, but separately from the lining. The fronts are extended, rolled back and faced to form the revers. The sleeves are in bishop style with narrow cuffs of lace. At the neck is a stock collar that closes invisibly at the center back. When the lining is omitted the shield is joined to the stock collar only, and attached to the fronts, under revers, permanently on the right and buttoned under the left. To cut this waist for a woman of medium size, 3½ yards of material 21 inches wide, 2¾ yards 27 inches wide, 2 yards 32 inches wide or 1¾ yard 44 inches wide will be required, with ½ yard of all-over lace, ½ yard of silk for revers, one yard of lace edging and ⅝ yard of insertion to trim as illustrated. The pattern No. 3784 is cut in sizes for a 32, 34, 36, 38, 40 and 42-inch bust measure; price 10 cents from this office.

3784 Shirt Waist, 32 to 42 in. bust.

Dr. Norton's Prescription.

"It wa'n't the first time that Dr. Norton and I had been on a case together, but I don't know 's we ever had one end in matrimony, the way this one did.

"No, I didn't do any nursing, this time. In fact, the Ellsworth sisters did n't know I had anything to do with it, except just to send the doctor there.

"I was in their house one day, and they was telling me how ailing and miserable they felt all the time. All at once I says, as though I'd only just thought of it, 'Why don't you try Dr. Norton? I'm most sure he'd cure you, and I know he wouldn't be exorbitant in his charges.' And then I went on to tell of the folks he'd cured. They thought it over some and guessed maybe they'd try him.

"'Don't you want me to send him over?' I says. 'He goes by quite often, and I'll tell him next time I see him if you want I should.'

"They said yes, I might send him, if I'd be so good. That was what I wanted, for I knew if I left it to them they'd keep neglecting it and would never have him.

"Well, it was a day or two later that I see Dr. Norton going by. I knocked on the window and he drove up into the yard and hitched his horse to the elm tree.

"Now we'd always been acquainted and we understood each other, so when he come in that day he looked at me and then he says, 'Well, Aunt Asenath, what have you got on your mind now?' and he settled down in his favorite chair real contented like.

"'The Ellsworth sisters want you to call there,' I says.

"'I suppose that means that you want them to want me to,' he says, laughing.

"I don't know's it makes any particular difference what you s'pose,' I says. 'It ought to be enough that you are wanted at the Ellsworths.'

"'Any of them sick?' he says.

"'No more than common,' I says, 'but you know they ain't none of 'em well, ever. I don't s'pose you'll take any advice from an old friend, but I'll tell you just what is the matter with 'em. They 're afraid as death of fresh air, and they don't have enough to do, and three women, so they don't bother to cook much and so they live on baker's stuff mostly.'

"The doctor sat for awhile without speaking, then he got up and put on his overcoat.

"'It is not good for woman to be alone. Good-bye, Aunt Asenath.' That

An absorbing chapter of inside political history, telling of the secret magnanimity that marked the behavior of two open enemies at a great crisis in their lives.

was every word he said, but I knew him so well that I felt satisfied and easy in my mind, and I was certain that the Ellsworth sisters were going to be cured.

"Dr. Norton told me so much about that visit, and the sisters told so much, too, that I know what happened most as well as if I'd been there.

"He went in and began to talk about their symptoms, and he asked lots and lots of questions. Pauline had sick headaches, most every day; Martha had trouble with her stomach, and Ruth had liver trouble and bad colds most of the time. He found they lived mostly on toast and tea and coffee, and they never stepped out of the house if they could help it.

"After he'd got all the information he wanted, he sat looking at the floor ever so long, and then he says, 'I will cure you if you will do just as I say for three months. Will you do it?'

"They all said they would, but that wa'n't enough for Dr. Norton. He tore a leaf out of his note-book and wrote on it, 'I solemnly promise to do exactly as Dr. Norton directs for three months.' Then he had all three of them sign their names to it. They was dretful conscientious women, and he knew they'd keep their promise, if it killed 'em.

"'Now,' he says, 'I'm not going to give you any medicine this time, but there's something I'm going to get you to do for me. You know that clump of pines I've got down back of your house? Well, I'm going to have them cut off. I want you to board the two men that are going to do the work.'

"'Oh, we couldn't—we're not able—' they begun, but he stopped 'em by reminding them of their promise. 'I'll bring the men over to-morrow or next day,' he says, 'so you can have their rooms ready for them. You won't need to be afraid of them,' he says. 'They've worked for me before, and I know they're honest, steady fellows. The only thing you'll want to look out for is to give them plenty to eat, for cutting wood gives anybody a ferocious appetite.' Then he got up and started out of the room.

"'Oh, by the way,' he says, as he put on his gloves. 'You must have the windows of your sleeping rooms opened a crack every night. The air here is perfectly vile,' and he went to one of the windows and reached up and punched his fist through one of the little panes of glass.

"After he'd gone I s'pose they had a terrible time. I guess they cried and took on for quite a while. But there was their promise, and there was them two men a-coming in a day or so, and they just had to stop feeling bad and go to work.

"The very next day the men came and went to work. The doctor had given them directions, and told 'em to get the three Ellsworths out of doors as much as they could. The wood lot was about half a mile back of the house, and the men pretended they couldn't spare time to come up to dinner, so the sisters must bring their dinner to them. Well, the sisters they was awful timid, and one of 'em didn't dare to go alone, and there wa'n't one of 'em that could be hired to stay in the house alone, so all three of 'em had to go with the dinners. Naturally the walk give 'em a good appetite, so when they got home they'd just eat a good hearty dinner themselves.

"The men they was real interested in Dr. Norton's cure, and they managed it somehow so that before a week had gone by the sisters would stay down in the woods and eat their dinner with 'em. They'd have a good fire burning, and fix some place for 'em to sit, and there all five of 'em would picnic. And it got so they'd stay half the afternoon maybe, and watch the men at work. Of course this was only on good days. When it was terrible cold or stormy, the men would come up to dinner.

"Well, it ain't no wonder the Ellsworth sisters begun to feel more like something. Being out doors so much, and the smell of the pine, and having some work to do, and the excitement of having some real live men in the family it was all bound to make a change in 'em, and at the end of two months they was just as well as any of us.

"I tell you Dr. Norton was tickled enough. He come in one day and sat and laughed till I got all out of patience with him.

"'Do you remember how they seemed the first of the Winter?' he says. 'Pale and pasty looking, shut up in an airtight house that smelled like the silent tomb, only louder, and if a bit of fresh air managed to get smuggled in they get out of the way of it as if 'twas the pestilence? Well, I went there to-day and found the house locked up and I couldn't raise anybody. I thought they'd gone visiting, so as my patients were missing, I thought I'd go down and see how my men were getting along with the wood cutting. Well, if you'll believe me, when I got down to the lot there were two of my patients at work on a fallen pine tree with a cross-cut saw; the third one was standing by with the measuring stick in her hand, and the two men were at work on the same tree cutting off the limbs. I stayed and watched for awhile, and then I came away. I couldn't bear to break in on the pastoral scene.'

"'Those are uncommon young men,' I says.

"'That they are,' he agreed. 'They've done wonders. I didn't expect they would understand what I wanted of 'em so well.'

"'They seem real likely young men, too,' I says, 'and I'm glad of it, for there may more come out of this than either of us thought of at first.'

"I had to laugh when I see how blank the doctor looked, and then how scared. "You don't mean it, Aunt Asenath,' he says. "You're just teasing me.'

"'Perhaps I be,' I says, 'but I've had a better chance than you have to see how things are going. You never can tell,' I says, real severe, 'what will be the consequences when you attempt to mix in with human affairs. You better not make any further mischief, though, trying to undo what you've already done.'

"I see I'd kinder upset him, and he went away looking real blue, but the next day he come in and he seemed to be feeling better. 'I've been thinking over what you said yesterday,' he says, 'and it seems to me if there is any blame you'll have to share it with me. But the more I think it over the less it worries me. Why shouldn't they get married, I'd like to know? And which ones are they?'

"'You're as curious as you ever accused me of being,' I says, 'but you'll have to wait like the rest of us. I'm sure I don't know which ones is interested in which ones, but unless I'm greatly mistaken something's going to happen sometime.'

"And I was right, though it wa'n't till a year afterwards that the wedding come off. It was the youngest Ellsworth girl. Some of the neighbors thought 'twas a terrible thing, but it didn't seem so to me. He was an honest, hard-working man, and they was fond of each other.

"Yes, they all live together, and Dr. Norton don't have to prescribe for 'em no more. It was a permanent cure."

BUSINESS BITS.

THE concensus of opinion in last week's issue seemed to indicate that it is advisable for fruit growers to own their own spraying outfit. Wm. Stahl, Quincy, Ill., offers a full line of spraying machinery. He will send you catalogue describing all insects injurious to fruit for the asking.

You can have a low-down wagon simply by getting a set of steel wheels to fit your farm wagon. It is surprising how cheap these wheels can be supplied. Empire Mfg. Co., Quincy, Ill., will send a catalogue free, telling how to measure for the size of wheel, giving prices and all.

THE Eclipse corn planter and fertilizer distributor is one of those machines that will save its cost every season for any farmer who plants as much as a half dozen acres of corn. It drops in hills or drills at the will of the operator, and will do the work of five men at hand planting. Write for free catalogue to the Belcher & Taylor Agricultural Tool Co., Box 75, Chicopee Falls, Mass.

THE International Food Co., Minneapolis, Minn., offers a $3,000 stock book free, the only conditions being that you answer four questions found in their advertisements. The book is valuable to all stock raisers, and the foods sold by this company are highly recommended by users as a conditioner. It is cheap, too—three feeds for one cent.

IT is impossible to have pure sweet milk, unless you remove the animal heat and stable and other odors. This is most readily accomplished by use of the Perfection milk cooler and aerator, which makes the milk smell sweet, taste sweet and keep sweet longer than if handled in the ordinary way. Send to the manufacturer, L. R. Lewis, Cortland, N. Y., for catalogue and prices.

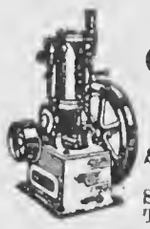
THE Kraus pivot axle cultivator possesses some excellent features which are peculiar to the Kraus alone. Each gang is provided with an independent lever for raising and lowering, and for controlling the depth of the shovels. The pivot axles enable the operator to control the direction of the cultivator completely. It changes direction instantly, and will "hug" a row perfectly either on level or hillside lands. It is equipped with either pin or spring shovels or spring teeth. Altogether it is one of the most durable and substantially-built cultivators on the market, and is of light draft, easy to handle and does most perfect work. Write for catalogue to Akron Cultivator Co., Akron, Ohio.

THERE is nothing that does more to set off and bring out the great beauty of home surroundings than a little bright paint applied to buildings, fences, walls, etc. A man is judged to a great extent by his surroundings and appearance, whether he is a farmer, a manufacturer or a financier. His ability is gauged a great deal by the appearance of his farm, the condition of his buildings, etc. He cannot afford to allow his buildings to look untidy and leave them unpainted. A paint made by the Casein Company of America, Bellows Falls, Vt., is called "Indurine." Indurine is a weatherproof, fireproof, cold-water paint. This means that it comes in the form of a dry powder, and that it is easily and quickly prepared for use by the simple addition of cold water. It is made in white and practically all colors. It is equally desirable for inside and outside use. Write the manufacturers for full information.

The nearest thing to a certain Cough Cure, is Dr. D. Jayne's Expectorant; and it is deceptively cheap: it takes so little of it to do the work.—*Adv.*

Cumberland Raspberry Plants for Sale or Exchange. P. SUTTON, Exeter, Luzerne Co., Pa.

THE ADMIRAL DEWEY POTATO Best this season. Yields Big crops. Ask for testimonials. 40c. per lb; 3 lbs., $1, postpaid; ex. or frt., peck, 75c.; 1 bu., $2; bbl., $5. Ad. Introducer, C. M. Robinson, Manorville, L. I., N. Y



CHARTER Gasoline Engine
USED Any Place By Any One For Any Purpose
Stationaries, Portables, Engines and Pumps, Hoisters
Send for Illustrated Catalogue and Testimonials. State your Power Needs.
Charter Gas Engine Co., Box 26, Sterling, Ill

ROUND SILO
THE PHILADELPHIA.
The only perfect continuous open-front Silo made. See Open-Top Patent Roof. Ask for catalogue. E. F. SCHLICHTER, 321 Vine Street, Philadelphia, Pa.
Also made in the West by DUPLEX MFG. CO., South Superior, Wis.

Wants, For Sale or Exchange

FOR SALE.

Country Home, "Rural Grounds,"
of the late ELBERT S. CARMAN, for many years owner and editor of The Rural New-Yorker.

Situated in the Hackensack valley, 18 miles from New York, one mile west of the station, River Edge, on the New Jersey and New York Railroad. House in excellent order with broad plazzas. Good stable and carriage room. The grounds, consisting of a little over two acres, are beautifully graded and planted with rare coniferous and deciduous trees and shrubs. A never-failing lake of pure spring water adds to the beauty of the grounds.

MRS. ELBERT S. CARMAN, of No. 5 West 82nd Street, New York, will answer questions and show views of the place

FOR SALE.—Finest little farm in Orange County. Good buildings; fine location. VAUGHAN, Monroe, N. Y

Farm Managers, Gardeners, Buttermakers, etc., always on hand. No charges to employers. Write us. Rural Science Agency, Durham, N. H.

100 FARMS FOR SALE WESTERN RESERVE FARMS in the Mahoning Vy. Send for list. Dennison & Miller, Warren, O.

Of Interest to Those who Wish to Engage in Apple or Peach Growing—Send for Prospectus of Fruit Company, organized for growing the celebrated "Albemarle Pippin" and other apples and peaches—a highly profitable business. The land acquired "probably the best tract in Virginia for a large commercial orchard." Managed by practical fruit growers. Full details given in Prospectus, with reliable data on yields and profits of many bearing orchards. Best references. Address PIEDMONT VIRGINIA FRUIT COMPANY, Lynchburg, Va.

Three Solid-Colored Jersey Heifers for sale, 3, 4 and 6 mos. old; sire a grandson of the great "Exile." J. A. HERR, R. D. No. 4, Lancaster, Pa.

Cure Barren Animals
THE LOSS SAVED IS CLEAR PROFIT.
Others Cure their Animals. WHY BUTCHER yours? Thousands of cows, mares, sows, etc., restored to breeding in the past 20 years. The best stock farms in the world are our patrons, why not you? ABORTION: Every cow that aborts should be treated with this remedy. You cannot afford to experiment, profit by the experience of expert breeders. Treatment by mail, $1.10. Other remedies just as reliable. Ask for circulars any way.
MOORE BROS., Veterinary Surgeons, Albany, N. Y

Barns of Plank save timber and cash. Best, cheapest, strongest. 4,000 in use. Book for stamp. SHAWVER BROS., Bellefontaine, Ohio

Oldest Commission House in New York Est. 1838.

Market Briefs.

PICKED UP HERE AND THERE.

"SPRING" LAMBS have been arriving more freely since the close of the Lenten season, and in some instances, better prices have been obtained, $6 or a trifle over being the top for the best now. The cool weather has been favorable for this country-dressed meat trade from the commission houses. A few days of warm, sultry weather would make havoc with this business, for dressed lambs sour and spoil quickly unless stored in a cold house. For shipment late in Spring it is advisable to cut the lambs open much more than in cold weather, as the danger of spoiling is thus lessened.

A BIG TOW FOR THE OCEAN.—A logging company in Oregon is about to undertake the preparation of a raft to contain 10,000,000 feet of logs, to be towed across the Pacific to the port of Shanghai, China. These logs will be worth over $200,000 in the Chinese market. The cost of towing will be only about $20,000, so that the venture will prove highly profitable if the journey is made in safety It is expected that the trip can be made with a 5,000-ton steamer in two months. There are great risks connected with this job, not the least of which is the possible danger to shipping, if the raft should be lost in a storm and drift into the pathway of other vessels.

WESTERN DRIED FRUIT MATTERS.—The troubles of the California cured-fruit associations are attracting unusual attention, and the causes of their difficulties should be studied by other associations, if they wish to avoid running against the same snags. The officers seem to have blundered in not keeping in close touch with the great markets and their own members. They allowed an excessive surplus of goods to accumulate on their hands, seeming to forget that prunes and raisins are grown in other parts of the world than California. The cut in price they have made relieves this condition somewhat, but it will unsettle the market for a long time. There is a very bitter feeling against the Prune Association. The courts have decided that under the circumstances growers are not legally bound by their contracts to the Association. The growers claim that the real conditions have been hidden from them. If this is a fact, the officials could not have made a worse mistake. The only way that an association composed largely of farmers can hold together and succeed is to invite discussion and keep the members informed as to what is being done. This may lead to cultivation and pruning in the shape of stormy meetings and the ousting of incompetent officials or those trying to hold their jobs by political methods, but it will weed out mistakes while they are small. To handle such an organization is no easy job. If one set of directors cannot do it, they ought to be willing to give others a chance; or, if not, they should be removed. The excuses made by some of these officials seem like nonsense. They lay it all to the publicity that has been given the matter. That is just what has been needed. Keeping their members in the dark as to what is going on may put off the crash for a time, but it is sure to come.

TOO GREEDY.—On general principles it is a good plan for the producer to get as near the consumer as possible, but this may be overdone, and some who raise produce for sale in city markets might well heed the old proverb about letting "well enough alone." A middleman who has made the business a study for years is better able to get high prices from retailers and avoid bad debts, than an outsider. Several mushroom growers had disposed of their output for some time through a reliable commission man in this city. He had got good prices for them, and made prompt returns. It seemed to be so easy that the growers got a case of "big head" and concluded that they might as well sell their own mushrooms and make the commission themselves. They put cards in each basket with an invitation to the buyer to correspond with them and buy direct. They succeeded in placing a large part of their output in this way, but soon complaints of inferior quality began to come from buyers who knew that they had an advantage over non-resident shippers, and bad debts piled up to the extent of several hundred dollars. They came to the man who formerly handled their goods and offered them again to him, but he declined, saying that he had taken considerable trouble to work up a trade for them, only to have it taken away, and he did not care to be bothered with any more such childish nonsense. A really careful and straight commission merchant is one of the best friends a farmer can have, and it is a good plan to stick to him and not grudge the commission he makes.

W. W. H.

EVAPORATED RASPBERRY TRADE.

The demand for evaporated raspberries is much lighter than several years ago, and we have no doubt that evaporating to any extent for market is somewhat a thing of the past. The reason is simple. They are now canned in large quantities, and when the market is at its lowest ebb. Much of the natural flavor is retained, and the goods being more serviceable, better quality, cheaper and less trouble than the evaporated goods, have run it out of the market THOS. H. EVANS & CO.

Baltimore.

It is likely there is not quite as much demand for dried raspberries as there was years ago, since there is a much greater production of California dried fruits. Evaporated raspberries are selling at from 18 to 20 cents, and we have no doubt many more would be used if price was 12½ to 15 cents. Those who raise and evaporate their own berries claim that there is a fair profit after the price goes above 10 to 11 cents. A number of years ago the price got down to 10 cents, on account of a very heavy production. Those who were raising the berries were discouraged, and many gave it up. WM. L. ALLEN & CO.

New York.

There are no statistics whatever as to the receipts, and we can only speak in a general way. Ten years ago the bulk of the crop was made in New York State, and came here for sale, and the price ranged from 25 cents down to 15 cents. Now there are a great many made in Michigan, and they and much of the New York State crop go to Chicago. The crops of 1897, 1898 and 1899 were so large that there was a surplus of not less than 50 carloads, and the price dropped down as low as 8½ cents. This discouraged the producers, and the crop of 1900 was small, so that now we are getting 19 to 20 cents. We have so many new fruits from California, at very low prices, that we wonder that raspberries sell as well as they do, and shall expect them to drop back to 10 cents if there is a good crop this year. You cannot advise farmers to plant largely again.

New York. A. C. WORTH.

GRAIN PROSPECTS.

Grainfields look well here, and grass would have stood the Winter all right, but it was very poor last Fall. The weather was not favorable last year for clover, so we have no clover in our new fields. We have a light sandy soil here; a little top-dressing after seeding will do very well for grain and grass. C. E. G.

Gibraltar, Pa.

Fall-sown grains and newly-seeded grass fields have stood the Winter well, having been protected to a certain extent by a covering of snow during our coldest weather. The prospects for the coming season are good at this date. The plan generally adopted with us is to sow to grass seed at the time of sowing wheat. Some prefer to wait until Spring; some prefer to mix clover and grass together. We make no special effort in that direction. We live in a fertile valley and have little trouble in obtaining a good stand of grass on all kinds of land. B. G. F.

Seville, O.

The prospects in this section for a good crop of wheat the coming season are excellent, as none to speak of has winter-killed. Grass has also stood the Winter well, but owing to the severe drought of last Summer a good catch was not generally secured; consequently, a full crop is not likely. As a rule our best stands of grass are obtained by seeding wheatfields early in the Spring, although in some cases good catches are secured by seeding with barley or oats, or with wheat in the Fall. Alfalfa is beginning to be grown here in a small way, and succeeds well where given a fair show. J. H. B.

Mandana, N. Y.

Pomelo vs. "Grape Fruit."

Among the delicious fruits of the orange or Citrus family is the pomelo. It is much larger than the orange, of slightly flattened shape and pale lemon yellow. The flavor is sour but very agreeable, being much milder than the lemon and with a touch of bitterness. The skin is very bitter and so are the partitions that separate the sections of edible pulp. But by cutting the fruit crosswise into halves and using a spoon to dip out the pulp there will be only a slightly bitter taste. There is no more wholesome and refreshing fruit, and it is especially desirable in Summer. The name pomelo is the correct one, and is always used for this fruit in the East Indies, whence it was brought to this country. "Grape fruit" is so inappropriate and inapplicable that it should never be used. It was given it in Florida about 20 years ago, and why no one seems to be able to tell with any sort of reason. Let the name pomelo be used by all intelligent people, whether in fruit or otherwise.

E. E. VAN DEMAN.

Ives Peach.

Having many inquiries as to the origin of Ives peach, I will give your readers a short account of this celebrated variety. About 30 years ago a single tree came up in the garden of my late father, I. M. Ives, a noted horticulturist of that day, from which I set out 200 trees. I have supplied fruit to Boston market for many years, until now I am unable to supply the demand. The variety is a dark red, freestone expressly for preserving, in which it excels all other varieties that I know. The fruit brings from $6 to $8 per bushel. The trees are very hardy, enormously productive and bear every year.

Salem, Mass. JOHN S. IVES.

The prices mentioned are far above the average, and could not possibly be maintained for a long period, because the supply, being easily increased, would soon bring them down. It may be that this is a valuable peach for general trial.

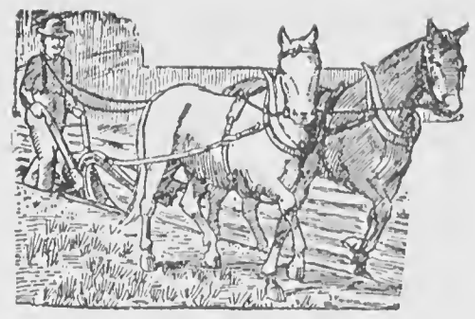
DR. PIERCE'S FAVORITE PRESCRIPTION

"I had been a sufferer for many years from nervousness with all its symptoms and complications," writes Mrs. O. N. Fisher, 1861 Lexington Ave., New York, N. Y. "I was constantly going to see a physician or purchasing medicine. In the spring of 1897 my husband induced me to try Dr. Pierce's Favorite Prescription. After taking one bottle and following your advice I was so encouraged that I took five more bottles, and then stopped for several weeks as I felt so much better, but still I was not *completely cured*. I commenced taking it again and felt that I was improving faster than at first. I am not now cross and irritable, and I have a good color in my face; have also gained about ten pounds in weight and *one thousand pounds of comfort*, for I am a new woman once more and your advice and your 'Favorite Prescription' is the cause of it, coupled with the 'Pleasant Pellets' which are not to be dispensed with. I took eight bottles of the 'Prescription' the last time, making fourteen in all, and will not take any more unless you so advise, for I do not see as I need it."

makes weak women STRONG, sick women WELL.



The Great Value

and the marvelous healing power of

Veterinary Pixine

has never been made more manifest than when in emergency a speedy and permanent healing ointment is urgently needed.

Apply it, rub it in on bare spots, inflammatory swelling, old sores, scratches, grease heel and speed cracks. It penetrates and soothes, and the horse grows well as he toils throughout the day.

Absolutely antiseptic—scientific, unfailing. Indorsed by stock-raisers and trainers throughout the United States and Europe. Investigate; money back if it fails.

Live Stock and Dairy

THE BREEDER'S WAYSIDE.

Breed of Cows for a Dairy.

What cows can I buy for a dairy to get best results? I have Jerseys and live near a town of 6,000 population; have 12 acres of land; great demand for milk. Would you advise Holsteins or Short-horns?

Waynesboro, Pa. G. H. H.

No more satisfactory breed of cows exists for supplying consumers with milk, than the Jersey. The milk is rated as strictly high class, when drawn from healthy cows, and Jersey milk is sold to the most particular trade in America. That from the consumer's standpoint. Now from the producer's standpoint, as to whether it will pay to keep one breed or another, depends mainly on the individual merit of the cows kept. The writer keeps Jerseys. Then by all means I should say, stick to your breed, get better cows if you can, and make a success of them. If you cannot succeed with Jerseys, then something is wrong with your method or management, for there are plenty of men maintaining Jersey herds and selling milk in towns who are succeeding in the business. If you can't make Jerseys go, then how do you know you can succeed with the other breeds? Your cows at four years old should be able to produce at least 5,000 pounds of milk a year, if you have good ones. Weigh the milk yield of each cow each milking, using a spring balance, and keep a record of the same. Then weed out the unprofitable milkers. When you buy, be sure that you get cows that are first-class milkers and from superior ancestry. Then the breed matter will settle itself.

The above is not intended as a special plea in behalf of the Jersey, but rather to stick to a breed already adopted. But to go further, Short-horn milk is popular for town consumption, and the better class of Holstein milk also is, although there are too many cows of this breed that produce low-grade milk, to make it the best sort for a particular class of customers, unless cows giving milk containing at least 3½ per cent fat are selected. A commendable effort is being made by Holstein breeders to produce strains yielding high-grade milk, and these cows will do for city trade. As a rule, however, the Holstein serves a better purpose as a producer of milk for creameries and butter making. The Short-horn usually will not produce milk as economically as either Jersey or Holstein, while the latter ranks as the greatest milk-producing breed in the world. Generally speaking, no matter what the breed, the cow which produces the greatest amount of milk in a day yields relatively speaking the milk poorest in butter fat. The Jersey that yields 10 pounds of milk ordinarily makes a milk richer in fat than the one yielding 35 pounds. People as a rule prefer milk rich in fat, for drinking or to skim for cream; consequently Jersey milk will supply this requirement better than Short-horn or Holstein. So this is another reason for adhering to the Jersey for this special phase of dairying.

If it is desired to keep some Jerseys and also some Holsteins, and mix the richer with the poorer milk, and so increase the quantity, and still reduce the quality, the scheme will work. Still, I assume that what is wanted is profit. The question arises, which will produce 100 pounds of milk cheaper, 1,000 pounds of Jersey or 1,000 pounds of some other breed? That point all depends on the individuality of the cow or cows. It is not necessarily a breed question entirely. The dairy breeds, to be sure, will produce this more economically than the beef breeds. The competition is closer among the purely dairy types. Yet on the basis of my knowledge of the subject, I do not hesitate to recommend the Jersey as a breed capable of yielding a very high-grade milk at as low a cost of production per pound as any dairy breed we have.

Concerning this, the question has been asked me: "Where the milk from various cows is mixed together, can we really guarantee it to be uniform, or will some customers get less fat than others?" This will depend upon conditions. If the milk from 50 cows, of several breeds, was thoroughly mixed together before distribution, it would no doubt be uniform in quality if bottled or dipped out from the can with long-handled dipper. However, if one had only half a dozen or so cows, representing two or three breeds, with extremes in quality, this milk might easily vary in quality if two of these cows should go dry for a time, or fall off greatly in milk yield. The greater the number of mixed cows kept, the less the variation. The writer believes that the live-stock interests of America will be more benefited by purity of breeding than by impurity. Therefore he advocates one breed for a purpose and fixed standards. C. S. PLUMB.

Short-horn and Aberdeen-Angus Cross

A man in West Virginia says he has obtained an excellent general-purpose cow by crossing Short-horn of good milking strain with an Aberdeen Angus, and my opinion is solicited on such a cross. This is what may be regarded as a harmonious cross, two beef breeds, of large type, being mated. Such a cross would naturally produce a better beef than dairy animal. The Angus is not regarded as the equal of the dairy Short-horn in milk production, but in this instance, fair milking blood may have been mated, and for the first generation satisfactory results have been secured. With the second generation uncertainty and trouble come in. I can see no advantage in crossing these two breeds, unless we view it from the standpoint of improvement through one individual, that is, not a good representative of the breed, by mating it with a better one of another breed. Fine typical Short-horns or Angus cattle would better be kept purebred or high grade. I certainly fail to see how Angus blood can improve a Short-horn of dairy type, that is, of high individual merit. In fact, Angus blood would ordinarily tend to the production of a type of animal away from rather than toward the general-purpose idea. C. S. PLUMB.

DISHORNING JERSEYS.—Would you advise dishorning Jersey calves intended for stock? How would you do it? J. E. D.

Yes, for practical purposes in the dairy we think dishorning is desirable. The loss of the horns might injure the sale of purebred animals, but they have no value on dairy cows. The whole process was explained April 13, page 277.

A TALK ABOUT PIGS.

The Size of Litters.

How many of the average litter are considered good enough to register? What proportion of the pigs do breeders usually reject? Do not the pigs from small litters usually make the best individuals? That seems to be the case in our experience, and we would like to know what others think of it. Some breeders say they would not breed a sow that had small litters, but we have found such pigs superior as they grew up.

Sometimes one and sometimes two pigs from litter are not good enough to register. Average about 10 pigs per litter. Undoubtedly small litters make the best individuals as a rule.

J. D. VAN VALKENBURGH.

Greene, N. Y.

About two-thirds of the pigs are usually good enough to register. Pigs from the smaller litter usually prove the best individuals. Litters of 12 or 14 are too many; eight or 10 are better. I prefer to save a sow pig for breeder from a litter of seven or more; eight or nine is a very good-sized litter.

Vermont. C. C. PAINE.

It depends greatly on the dam and sire, number in litter and many other conditions. Sometimes, if the litter is not too large, 100 per cent is fit for breeding purposes, but very rarely; usually from 10 to 80 per cent. Breeders do not raise near as many as they ought to. Both for breeders and for the economical production of pork I would rather have five *good* pigs than 12 poor ones. C. K. RECORD.

Peterboro, N. Y.

The number of pigs that are good enough to retain for breeders varies very much, as some sows breed better than others. I have certain sows that will produce 85 per cent show pigs, and others, in some breeders' herds, would only farrow 45 per cent good enough to retain for breeders. I think that the litters do not necessarily have to be small to raise the choicest pigs; however, it is seldom that a litter of more than six pigs contains pigs of exceptional size and development for their age. I like my sows to farrow litters that will average eight pigs, however, and they usually do. D. R. PERRY.

Columbus, Ind.

The golden rule is our motto. About one-half of the average litter is generally not good enough to register, though some breeders do not cull so heavily. We reject all that are not strictly first-class, and good enough to register and send the culls to the butcher. The pigs from small litters sometimes make the best individuals, but the feeder is to blame for that. If the male is vigorous and the sow properly fed from the time she is bred until she farrows the pigs will not be inferior when farrowed. If the pigs are inferior when farrowed the feeder is directly or indirectly to blame. If we thought small litters developed into the best hogs we would henceforth argue in favor of small litters. The best pig in the litter at one month old does not always make the best hog; sometimes a pig that is slow to develop the good points retains them best when fully grown. G. A. FOOTE & SON.

Irvington, Ky.

Holding a Switching Tail.

Fig. 125 represents a device that I have found to be particularly useful in the cow stable at milking time to prevent a bothersome cow from annoying a milker. The whole device, as figured, comes very near to showing just what it is without description. If desired, it can be made entirely out of rope, but as the reader will observe, a small piece of chain is used to connect the two ends of the rope. I rather like the addition of the chain, because it gives a little weight that aids much in holding the rope in place. There is also an advantage in fastening one end of the chain securely to the rope, while the other passes through the loop in the rope end, and doubles back. This makes it very easy to lengthen or shorten the circle without much trouble. As will be seen, the rope is thrown over the hook points, and hangs down just above the udder, holding the tail in between the legs. Once in a while a cow will get the tail out of the device, but it is comparatively infrequent. I have used this rope quite often on a cow at my back, to prevent her swinging the tail into my face while milking the next cow to her. A nervous cow will frequently do this even in the Winter just to keep the milker located, something as a "feeler." This can be used on a kicking cow very readily, and especially those that will be liable to kick if they find their tail is fastened. The probabilities are the cow will get the tail loose before she becomes so agitated as to kick. Every milker ought to have one or two of these devices in the stable, and once with them he will not be found without it. It is preferable that the rope be made of inch stuff, and rather a light-weight chain Size is a matter that depends entirely on the size of the cows.

Shiawassee Co., Mich. C. P. REYNOLDS.

MILK FARMERS AHEAD.

The Scranton Dairy Company Settles.

The dairy company, after making contracts with the farmers for one year, claimed that the express company would not give them rates less than New York price, which is 26 cents per can, but this proved to be untrue, for the railroad company offered the farmers rates, as soon as they commenced to make butter, to both Scranton and La Plume, where the dairy company's condensery is located. On January 1, 19 of the 82 farmers who furnished milk to the dairy company held a meeting, and decided to commence making butter in the new factory, which was built in the Fall, costing the farmers $4,000. This building and machinery was rented to the Scranton Dairy Co. when they made contracts for the milk at $300 per year, but they gave up the lease when they quit taking the milk. On December 31 we hired an experienced butter maker and put him at work, paying him $50 per month till April 1. It was rather up-hill work for a spell, but we kept getting more milk, till now we have 75 cans per day. January and February our milk netted us two cents per quart. The dairy company did not pay for December milk on January 1, as they had agreed to, but about February 1 offered 70 cents on the dollar, and the report was that the company had sold out and gone out of business, which was true in part, as they had sold their retail business in Scranton and tried hard to sell the condensery at La Plume but failed to do so. About 60 farmers took what the company offered, or the 70 cents on the dollar, but the rest held out, and commenced suit against the company, and the first week in April the company paid them in full and interest from January 10 to date, also costs to amount of $91. Now, those who took the company's offer are feeling sick. The size of the thing is that the company could not sell its condensed milk so as to get out whole, so tried to make its loss good by squeezing the farmer. The 30 per cent that the farmers lost amounted to about $800.

The Improved United States Separator

as it appears on the market to-day is the result of years of study and experiment. While we do not claim it is perfect, although many users say it is as near perfection as possible, yet we do claim that it is unequalled by any other make on the market. This claim is based upon its work at Experiment Stations and in Dairies and Creameries the country over, where it has demonstrated many times that it

Does more exhaustive skimming, therefore Saves Cream:
Has greater capacity according to price, therefore Saves Time:
Requires less power to run and less time to clean, therefore Saves Labor:
Has greater simplicity and durability, therefore Saves Expense.

In fact it has so many times proved in competition with other makes its overwhelming superiority as to make good its right to be known as

The Standard Cream Separator of the World

If you will follow the advice of its users you will investigate its merits before buying some other make said to be "just as good." Remember there are none such.

We also sell a complete line of Dairy and Creamery Apparatus.
Write for descriptive catalogues of what you are in need of.

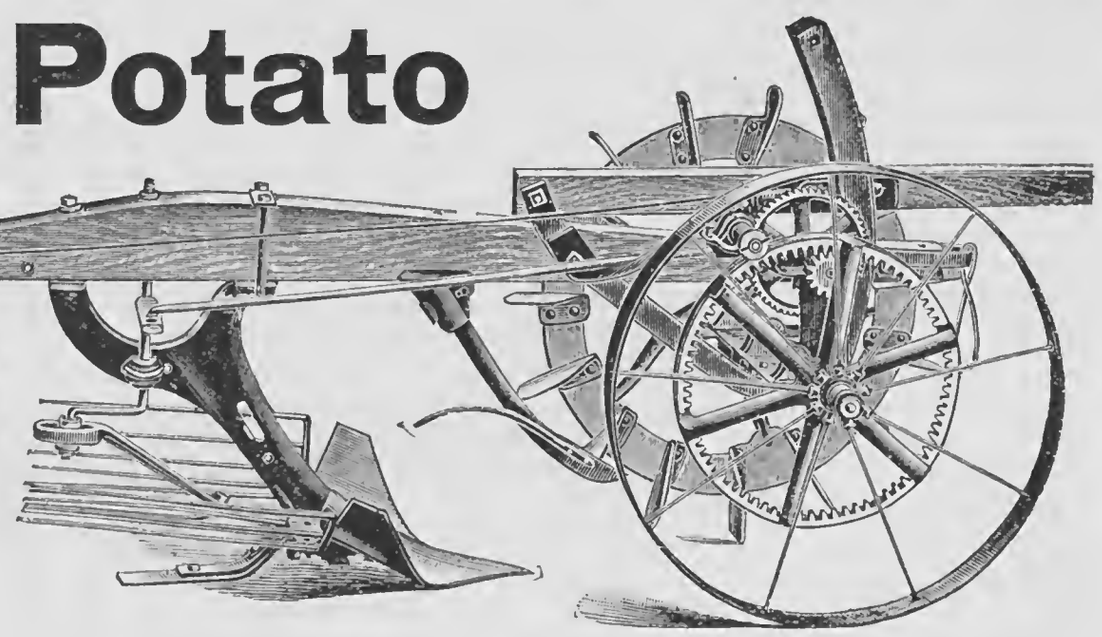
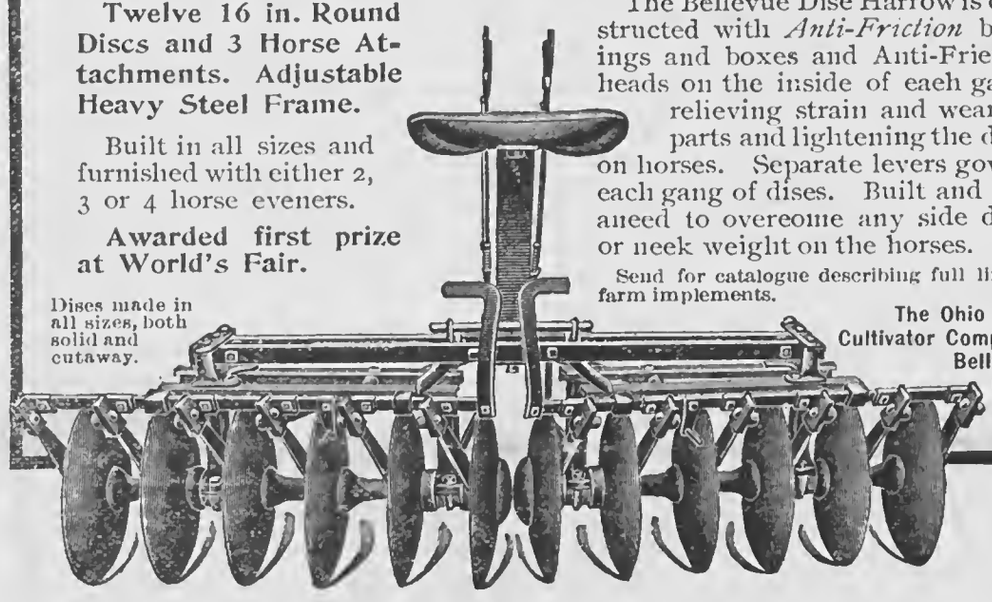
ORNAMENTAL FENCE

25 designs, all steel. Handsome, durable.—Cheaper than a wood fence. Special inducements to church and cemeteries. Catalogue free.
KOKOMO FENCE MACHINE CO., 454 North St., Kokomo, Indiana.

O. K. Potato DIGGER


(Patent Applied for.)
Guaranteed to do as good work in the same field as any four-horse elevator digger on the market. Price one-half. Draft one-half. Cost per year for repairs, one-fifth. Guaranteed to dig as clean as a man can with a fork. Will make digging potatoes as easy, simple and inexpensive as cutting grass. Would such a digger please you? Will you buy such a digger? WE TAKE ALL THE RISK—unsatisfactory work in your field means no sale. Every farmer who grows five acres or more of potatoes is interested. We wish to hear from all such. D. Y. HALLOCK & SONS, Box D 805, York, Pa.
(Please mention box number.)

The BELLEVUE Anti-Friction Disc Harrow
Twelve 16 in. Round Discs and 3 Horse Attachments. Adjustable Heavy Steel Frame.
Built in all sizes and furnished with either 2, 3 or 4 horse eveners.
Awarded first prize at World's Fair.


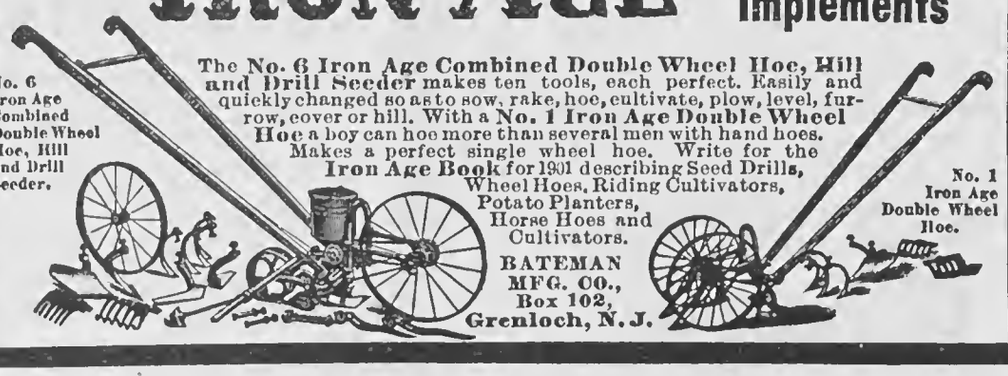
The Bellevue Dise Harrow is constructed with *Anti-Friction* bearings and boxes and Anti-Friction heads on the inside of each gang, relieving strain and wear on parts and lightening the draft on horses. Separate levers govern each gang of dises. Built and balanced to overcome any side draft or neck weight on the horses.
Send for catalogue describing full line of farm implements.
Dises made in all sizes, both solid and cutaway.
The Ohio Cultivator Company, Bellevue, Ohio.

A Good PLANTER
should plant all kinds of field seeds,
Field, Ensilage and Sweet Corn, Peas, Beans, Sugar Beets, Stock Beets, etc.
It should plant in hills, drills or check at the will of the operator. It should at the same time drop or drill all kinds of commercial fertilizers, wet, dry or lumpy, pulverized hen manure and other home made fertilizers, evenly in any quantity per acre.
EASILY ADJUSTED. EASY TO HANDLE. WEIGHS 150 LBS.

The Eclipse
Corn Planter and Fertilizer Distributer
does all this in the most perfect manner. Drops seed from 6 to 45 inches apart. Will distribute from 50 to 450 lbs. of fertilizer per acre. They are strongly built of good material and will last indefinitely.
Write for free catalogue, circulars, etc.
THE BELCHER & TAYLOR A. T. CO.
Box 75, Chicopee Falls, Mass.

GOOD INVESTMENTS

Here are four popular implements of the IRON AGE line. Don't forget that we make many others with which it will pay you to get acquainted. The Iron Age Pivot Wheel Riding Cultivator does good, steady work for years because it's built of good materials, and doesn't wear shaky. Fine for hillsides or crooked rows. The Improved-Robbins Potato Planter plants 4 to 7 acres a day, better than hand work.

Iron Age Pivot Wheel Cultivator.
Improved-Robbins Potato Planter.
IRON AGE Farm and Garden Implements


No. 6 Iron Age Combined Double Wheel Hoe, Hill and Drill Seeder.
The No. 6 Iron Age Combined Double Wheel Hoe, Hill and Drill Seeder makes ten tools, each perfect. Easily and quickly changed so as to sow, rake, hoe, cultivate, plow, level, furrow, cover or hill. With a No. 1 Iron Age Double Wheel Hoe a boy can hoe more than several men with hand hoes. Makes a perfect single wheel hoe. Write for the Iron Age Book for 1901 describing Seed Drills, Wheel Hoes, Riding Cultivators, Potato Planters, Horse Hoes and Cultivators.
BATEMAN MFG. CO., Box 102, Grenloch, N. J.
No. 1 Iron Age Double Wheel Hoe.

TRANSPLANTING MACHINES
transplant all kinds of plants, such as cabbage tobacco, sweet potatoes, tomatoes, sugar beets, watering and fertilizing at the same time; also has potato planting attachment. Write for prices and territory. Made by
THE NAGLEY MFG. CO., Lyons, N. Y.

Farmers, Take Warning!
Our patent, No. 600,782 of March 15, 1898, has been sustained by United States Circuit Court. This gives us the sole right to manufacture weeders having teeth [illegible] upper part and either round or substantially round in lower part [illegible] hereby notify farmers and dealers that any one using or selling th[illegible]nging goods are in danger of prosecution. We ask those selling our weeders to give us names of parties handling the infringing goods.

THE RURAL NEW-YORKER

A JOURNAL FOR THE SUBURBAN AND COUNTRY HOME

VOL. LX. No. 2675. NEW YORK, MAY 4, 1901. $1 PER YEAR.

LIME AND SULPHUR FOR PEAR BLIGHT.

MR. PEASE GIVES FURTHER INFORMATION.

Great Interest in the Subject.

The recent article by Mr. Pease on Pear blight has very deeply interested me. His experience, to say the least, is a remarkable one. To lose nearly 20 per cent of his trees, after such persistent efforts to check it as he used, seems almost incredible. I would like to ask Mr. Pease whether he disinfected the pruning tools when cutting out blight, also whether he cut much below the part affected? He says, apart from Bartlett and Louise Bonne, that the other varieties were affected about to an equal extent, except the Seckel, which was less so. Now, in my experience, the Angoulême has been virtually blight-proof—far more so than the Seckel. So it would seem that the attack of this trouble was a very virulent one with him, or else the disease was transmitted from the pruning tools. Will Mr. Pease state what proportions he uses of sulphur and lime, and the quantity of same to 50 gallons of water? I purpose giving this remedy a thorough trial and hope that I may have as favorable results as he has had.

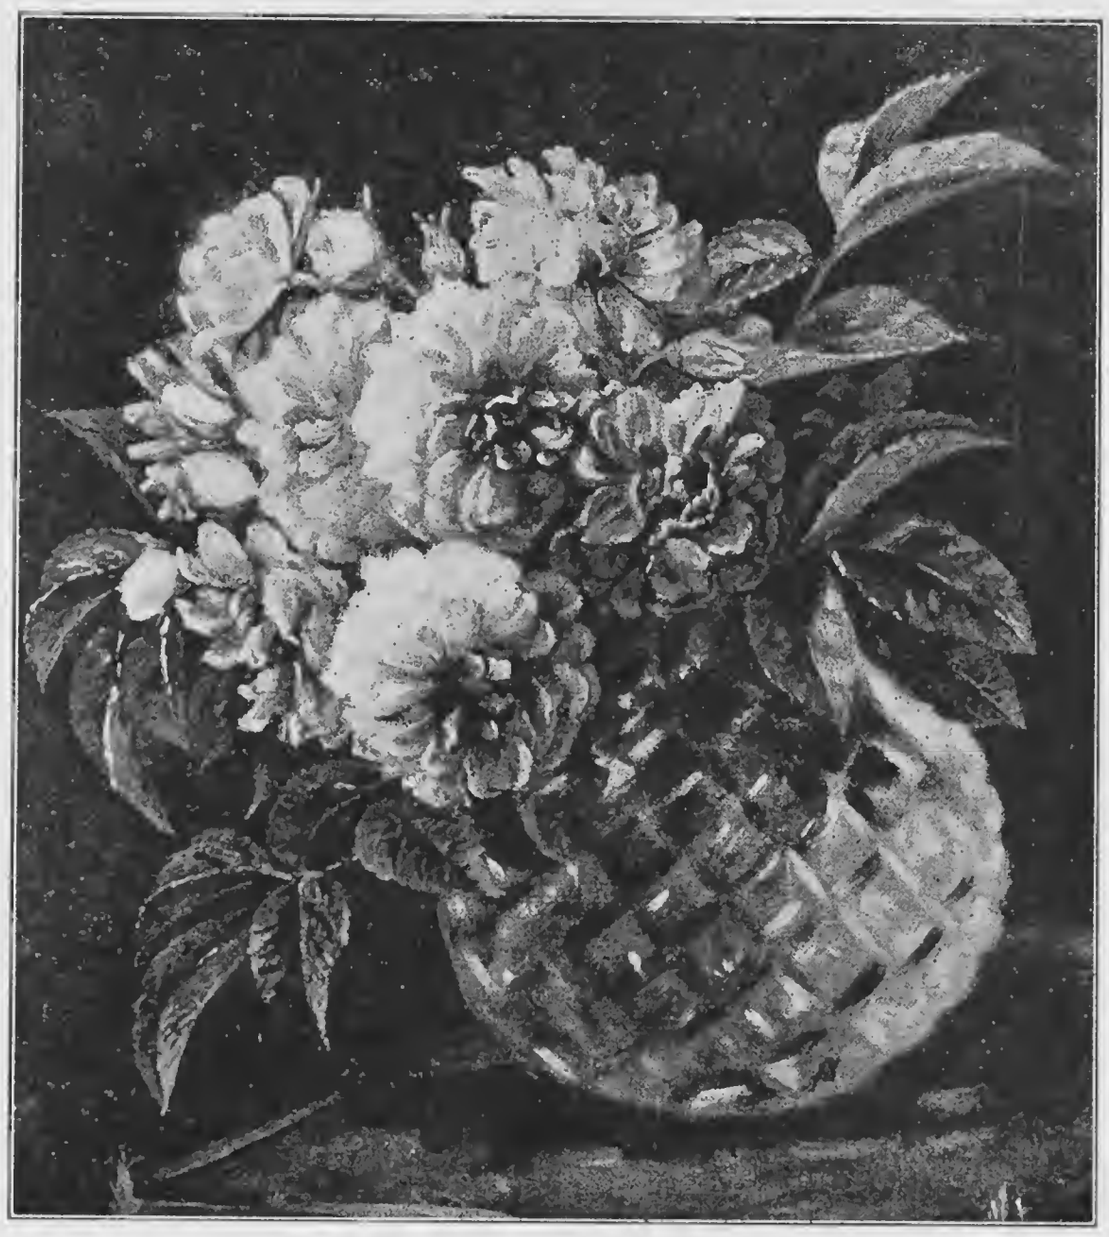
Orange Co., N. Y. J. R. CORNELL.

Mr. Cornell seems to think it almost incredible, that we should have met with such a loss of trees, with thorough treatment for the disease. To make this better understood I wish to call attention to the condition of the trees. They were planted in the Spring of 1893, and were attacked by blight in 1897 at the age of four years from planting. They had been cultivated thoroughly, and cut back closely every year up to this time, causing a rapid growth of wood, and making an ideal condition for the spread of the disease. In regard to spreading the disease by the tools used in pruning, I think this point has been practically settled. It has been shown by careful experiments that it is very difficult to spread the disease in this way, even by the most careless work. We did not deem it necessary to take any such precaution, but we were careful to cut a safe distance below the blight. For further proof I will say that we rarely find blight on the part of a limb left where blight has been cut. As to the susceptibility of the different varieties to the disease, I will say that in my previous article the statement was made in a general way, as I have not taken the pains to figure out the exact per cent of loss of each variety, but judging by observation I think the Angoulême would have shown the smallest per cent of loss (except the Seckel), but was far from being free from blight. We certainly did not carry the disease to the Angoulême trees by the pruning tools, because it was there before the tools were used. As to the remedy, I will state how we prepared it, and wait for further experience to improve upon our method.

For the wash, use a thick whitewash of lime with flower of sulphur thoroughly stirred in, adding one quart of strong brine and one-half pint of linseed oil to three gallons of wash. Make it very strong with sulphur. For the spray use milk of lime (strained) with from five to seven pounds of flower of sulphur to 50 gallons of mixture. It must be well stirred while using. As to the proper proportions, we are yet in the dark. This must be settled (if at all) by future work. I realize that we have opened up a great question and a broad field for investigation. The more I study the matter the more it seems to me that the cutting-off treatment is like locking up the barn after the horse is stolen. It is very evident that the disease is in the trees for some time before we have any outward evidence of it. I have found trees that were apparently all right in the Fall, black from the disease the following Spring. It seems to me the better way to use a preventive, if possible.

In my correspondence with scientific men one says that "the difficulty in controlling Pear blight by any application of sulphur is to get the sulphur where the germ is. The germ is inside the cell. There is no way of getting the sulphur to that place." Another says: "I am interested in what you have to say about the treatment of Pear blight, but I frankly confess that I doubt the effectiveness of the treatment with lime and sulphur. I would like to see good experimental evidence supporting it. I doubt it for this reason. It has been proven conclusively that this disease is caused by bacteria, exceedingly minute organisms which make their attacks upon the young growing tissue, as for example, the tender parts of the flower or tips of the young twigs. The germs get in at these tender places, and when once within the tissues work downward into the larger branches and limbs. Now it appears plain that any spray or wash, to be effective in keeping out these germs, must be applied at the point where they enter, and a wash applied to the trunks and limbs would not, of course, reach the most essential point. It seems probable that any spray, to be effective against this disease, must be applied while the flowers are open, because it is very evident that bees carry the disease from tree to tree as they visit the flowers." It is my opinion that we may get the sulphur on the trees by a wash or spray, or both, strong enough to destroy the bacteria before they can gain an entrance. In the interest of the pear growers, I feel that we have a right to ask these representatives from the experiment stations in this State, to give a *reasonable* reason for their doubts of the efficiency of this plan. The question has been asked whether we could not use poison with the spray also, to kill the Codling moth. I can see no reason why it could not be done if we were spraying at the proper time. And again, I do not know any reason why we might not use the sulphur with the Bordeaux Mixture when it seemed advisable to do so. I can say that I have seen marked effects of the sulphur spray on leaf blight of the pear, so that we shall have some benefit from our work, even if it should prove an ineffectual remedy for fire blight. I have great esteem for the work of the scientist, and I trust that in the near future some of them will come to our assistance with helpful suggestions along the lines indicated.

D. R. PEASE.



HYBRID RUGOSA ROSE NEW CENTURY. FIG. 128. SEE PAGE 326.

SPRAYING FOR MELON BLIGHT.

Several readers have asked what experiment station bulletins will give them information about melon diseases. After reading the article on page 265 other readers ask what is meant by the "one to 12 Bordeaux formula." F. A. Sirrine answers these questions as follows:

The New York Experiment Station has published no bulletin or pamphlet on melon blights. Short articles describing the characteristics of the leaf blights of melons have been published in the annual reports of New Jersey (New Brunswick), Connecticut (New Haven) and Massachusetts (Amherst) stations. In addition these diseases have been described in several bulletins of the Ohio (Columbus) and in one bulletin of the Colorado (Fort Collins) stations. The principal trouble described as affecting melons in New Jersey has been an anthracnose. In Connecticut and Massachusetts it has been the leaf blight called Alternaria. In Ohio the Downy mildew and Alternaria have caused the principal damage, while the Colorado writer describes the blight as "Cantaloupe blight." Probably it will be best to send for bulletins 73 and 105 of the Ohio Station for the description of the disease and for results of treatment. The other articles mentioned describe the disease, but give very little with regard to treatment for it.

It would seem that the best method for melon growers, and especially those who grow muskmelons, to follow would be to test the value of spraying on their own fields. The work done by Holmes Brothers showed that although they sprayed for Downy mildew, the leaf blight known as Alternaria was checked. I am sure that it will pay growers of muskmelons to spray their vines with weak solutions of Bordeaux Mixture to protect them from the striped beetle, and as the so-called Alternaria "leaf-blight" is liable to start early in the season the gain from spraying is doubled. By weak solutions of Bordeaux Mixture we mean the use of only two or three pounds of copper sulphate, or blue vitriol, to a 50-gallon barrel of water. It is customary with writers on spraying to speak of the 1-to-8, 1-to-11 and 1-to-12 formulas of Bordeaux Mixture. This is a short way of expressing the use of one pound of the copper sulphate to eight, 11 or 12 gallons of water. Spray pumps are usually mounted in barrels holding from 50 to 52 gallons, and generally only about 48 gallons of liquid are put in a barrel, hence a 1-to-8 formula would mean that six pounds of copper sulphate were used in a barrel holding 48 gallons of water, and the 1-to-12 means that four instead of six pounds of copper sulphate are used in the same-sized barrel. The 1-to-12 formula of Bordeaux Mixture is strong enough to use on muskmelon vines at any time,

and it is safer to use only half this strength while the vines are small. A large excess of lime should not be used in preparing these solutions, as the application of too much caustic lime, either dry or as combined in Bordeaux Mixture is liable to stunt young muskmelon vines. (See page 20 of Bulletin 158, New York Experiment Station.) It is advisable for all growers to commence spraying their melons as soon as they are out of the ground with a weak solution of Bordeaux Mixture, two pounds of copper sulphate to 48 gallons of water (1-to-24 formula) and repeat this application every week until the beetles disappear. As soon as the plants commence to form vines, spray with a stronger solution, 1-to-12, of Bordeaux Mixture, every 10 days or two weeks until the last settings of fruit are nearly mature. The early sprayings will discourage the beetle and leaf blights, while the late sprayings will help to keep off the Downy mildew and anthracnose. It is best to use the 1-to-12 formula for spraying strawberries.

THE "SEED END" OF POTATOES.

In Mr. Brown's interesting article entitled "Potato Growing in Central Illinois," on page 285, he says: "The seed or blossom end of each potato should be cut off and thrown away," and there he leaves the matter. Not a word as to the why and wherefore which we Yankees consider of the first importance. Every intelligent cultivator desires to give a substantial reason, backed up by facts, for whatever he does, and is seldom willing to "go it blind." Apropos to this matter there will be found in the Massachusetts Agricultural Report for 1886 an account of an interesting series of experiments, covering six consecutive years, by Edmund Hersey, of Hingham, Mass., read before the State Board of Agriculture. According to statistics the Nation has made a marvelous growth in 15 years. Can it be possible that the stem end of the potato has outstripped the seed end in the same ratio? Mr. Hersey's experiments were accompanied by 49 photographic views of the plants June 28 and July 21, and the season's product. These views show that the seed-end plants were more than double the size of the stem-enders on the same dates. Every year of the six the seed-enders started in advance and kept ahead of the stem-enders.

Now for the results. "The seed end produced (in one year) of large potatoes, four pounds eight ounces, and one pound 10 ounces of small; total, six pounds two ounces. Stem end produced of large potatoes four pounds four ounces, and of small one pound two ounces; total, five pounds six ounces. For six years the 10 hills of each produced—seed end, 166½ pounds of large potatoes and 47¼ pounds of small; total, 213¾ pounds. Stem end produced 141⅜ pounds of large potatoes and 47⅛ pounds of small; total, 188½ pounds—the seed end producing 25 pounds more large potatoes than the stem end, and about the same quantity of small potatoes. Rate per acre, seed end, 408 1-3 bushels; stem end, 358 1-3 bushels." Mr. Hersey summarizes the results of his experiments as follows: "Years of close observation and careful experiments lead me to the following conclusions: Whole potatoes will produce a crop from a week to 10 days earlier than cut potatoes. Small whole potatoes will produce for many years in succession just as good, if not better results, than large potatoes cut the size of the small whole ones. The seed end of a potato is better to plant than the stem end, because the plants start with more vigor, and produce larger and more potatoes. A large piece of a potato is better to plant in ordinary soil, and will produce a much better crop than very small pieces or single eyes." And yet I am told that some of our Connecticut farmers insist upon cutting off the seed end of the potato and throwing it away when preparing the tubers for planting! H. H. BOARDMAN.

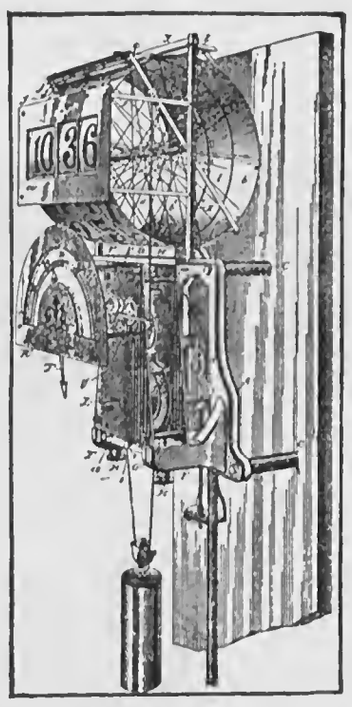
Connecticut.

SOME LAW AS TO TREES.

A tree is wholly the property of him upon whose land it stands, notwithstanding the roots extend into, or the branches overhang, the land of the adjoining owner, say the New York and other State courts. In Vermont is was held that the location and property of the tree should be determined by the position of the trunk or body above the soil, rather than by the roots within or branches above it. Permitting the branches of trees to extend beyond the soil of the owner is said to be an unequivocal act of negligence, warranting the party injured in abating the nuisance by clipping the branches back to his line of easement. It seems that he may also abate the roots projecting into his soil, at least if he has suffered actual damage. But here the law makes a curious distinction. After clipping the branches he cannot carry them, and the fruit they contain, away and convert them to his own use. There is no authority in anyone to treat as a nuisance that which is not so, and anyone assuming to abate as a nuisance that which is not so, acts at his peril. An adjoining owner may sue for damages, but unless the tree or trees are poisonous or noxious in nature, there must be proof of some real sensible damage to authorize him to maintain such action. In the case of C. vs. L., 24 Hom. (N. Y.) 405, the complaint alleged that in consequence of the overhanging limbs the plaintiff's crop was diminished by reason of shade. The court held that the plaintiff's remedy was by clipping the branches, especially if the owner of the tree refused to do so when requested.

It seems that a land owner is liable for damages growing out of his having planted on his own ground a yew tree (poisonous to horses) so near to his neighbor's lot that his horses while feeding on the branches overhanging were poisoned and subsequently died from the poison contained therein, solely on the ground that the tree was poisonous. But where a land owner clipped a yew tree, knowing it to be poisonous, and took so little care of the clippings, as to allow them to be placed on land not occupied by him, whereby the horses of plaintiff were poisoned, the defendant was held not liable.

An adjoining owner has no title to the fruit growing upon the branches of the trees which overhang his land, and will be liable in trespass for gathering it, say the Connecticut and New York courts. And further, says the court: "And he will be liable for an assault and battery for using violence to prevent the owner of the trees from gathering it, provided the latter cannot do so without committing a trespass." Even though fruit falls from the overhanging branches upon his land, the owner of the trees may go upon the land and take it away without being liable for trespass. But here the law exhibits another curious distinction, in that if, when pruning the trees, the loppings fall upon the adjoining land, the owner cannot enter and take them away, if by using due caution their falling there might have been prevented. So, if one's tree be blown down and falls on the land



A CLOCK WITHOUT A DIAL. Fig. 129.

of his neighbor, he may go and take it away, and the same rule prevails where fruit falls on the land of another; but if the owner of a tree cut the lopping branches so that they fall on another's land, he cannot be excused for entering to take them and the fruit thereon away, on the ground of necessity, because he might have prevented it. R. D. F.

EVERYBODY'S GARDEN.

PLANT PROTECTORS.—An indispensable adjunct to growing first early vegetables is a supply of plant protectors. Heavy tarred building paper, everything considered, is the most desirable material. It is sold here at 75 cents per roll, and the protectors can be made, labor included, for from 1½ to three cents apiece. Cut the material lengthwise or crosswise of the breadth, as will cause least waste, any length or diameter desired. Bind the strips round with one inch lap; with a sharp knife make an incision through both ends and fasten with brass paper fasteners. Covers of the same material are made by cutting into squares a little larger than the diameter of the protector. They are very useful in windy weather to prevent the plants from whipping, and plants thus protected when cold and stormy may with safety be set 10 days or two weeks earlier than otherwise. When desired for use, the covers may be held in place by slightly weighting with earth. When through using, the fasteners may be removed, and the strips packed away under weights. They will many times repay their cost each year, and low ones (say four or five inches high) left permanently around the Hubbard squash hills are almost a guarantee against the Black squash-bugs.

NOVELTIES.—Much pleasure and profit may be gained by testing some of the novelties sent out by reliable seedsmen. Give the boys and girls a little space in which to grow them. Substantial prizes are offered for fine specimens, good reports, names, etc., and there is no better way in which to interest all members of the family in garden work than striving to carry off some of the prizes.

SPROUTING SWEET CORN.—April 10, 1899, found considerable frost in the ground in this locality. On April 20 sweet corn (Early Sheffield) was planted, which was well up and cultivated on April 28. The corn was sprouted before planting by placing a layer of sand in shallow pans. Over this cheesecloth was spread, and the corn placed on the cloth; another layer of cloth was placed on top of the corn, and the whole covered with a light layer of sand. It was kept in a warm place, and well watered, and was nicely sprouted in five days, and planted on above date. July 8 we had corn for table use, and began marketing on July 15. The chief advantage of sprouting is that it can be planted much earlier without danger of rotting before germination takes place. This variety is very desirable, extra early, very hardy, withstanding some frost, and nearly free from smut. The ears are large and very fine in flavor.

EARLY TOMATOES.—With the hotbed and plant protectors, the problem of early tomatoes is solved. Sow early in the hotbed and transplant when the second leaves appear into rows two or three inches apart; they will find room to grow without crowding for some time to come. When grown sufficiently to begin to crowd transplant into pots. With broken bits of pot placed in the pots for drainage, fill them one-third full of rich soil; as the plant is placed in the pot place a small handful of Jadoo fibre under and around the roots. Add soil enough to hold the plant in place and firm down well around the roots, and fill up with loose soil. Do not pack or firm the soil about the stems. Place the pots in a tub partially filled with water which has been exposed to the sun, and when thoroughly soaked from the bottom upward place in the cold frame. With frequent watering and uncovering on warm days they will make the stem and root growth so essential to early fruiting. Jadoo fibre is an ideal preparation for potting, and when picked up and fined by working through a coarse sieve has no equal within my knowledge. When ready for the open ground, dig holes large and deep enough to hold the entire contents of the pots. Soak the pots thoroughly and jar out; if carefully done the roots now grown through the entire mass will hold it intact. Place in the hole and fill up with loose soil. Set out in this way, the work may be done under the hottest sun, and the plants will never wilt or change color. They will receive no check, and with the plant protectors for cold days or cold storms they may be safely transplanted two weeks earlier than they otherwise could. Compared with reports from the Lansing (Mich.) Experiment Station, we ripened same varieties fully three weeks earlier, from seed sown from three to six days later than theirs.

Michigan. J. E. MORSE.

CUT AND DRIED.

A New Form of Clock.

The American Inventor describes a new clock—a picture of which is shown at Fig. 129. Instead of having a hand passing around a dial this clock prints the time, minute by minute, in plain view. Those who have seen the registers on electric cars will understand how these figures appear. The picture gives an idea of the "works" of this clock. It seems to us that there is every reason why this system of indicating time is better than the old dial plan.

The Baldwin Apple and Spraying.

In New England, when the hill farmers wish to give you their best, they will bring you a dark red, solid, rich Baldwin apple. Some things grow better as they go away from home, but this is not true of Baldwin. It was born in Massachusetts, and it still reaches its highest perfection on the hills of its native State. During the early Winter many of the cellars under the New England homesteads are great pits of perfume. They are well stuffed with apples, and as you open the door a flood of fragrance rushes out. Western New York is a great apple country—settled originally by Yankees. The Baldwin apple is largely grown there, too, yet it has not been regarded as a first-class eating apple until recently.

"Why," said a large grower in Orleans County, "up to this year none of our best farmers thought of storing Baldwins for their own eating. They were good enough to sell, but not good enough for home use."

"What do they use?"

"Spitzenberg, Northern Spy and Greening are the favorites."

"Did you say some of them have eaten Baldwins this Winter?"

"Yes, continued spraying has greatly improved Baldwin—there is no question about it. It has improved in size, quality and appearance!"

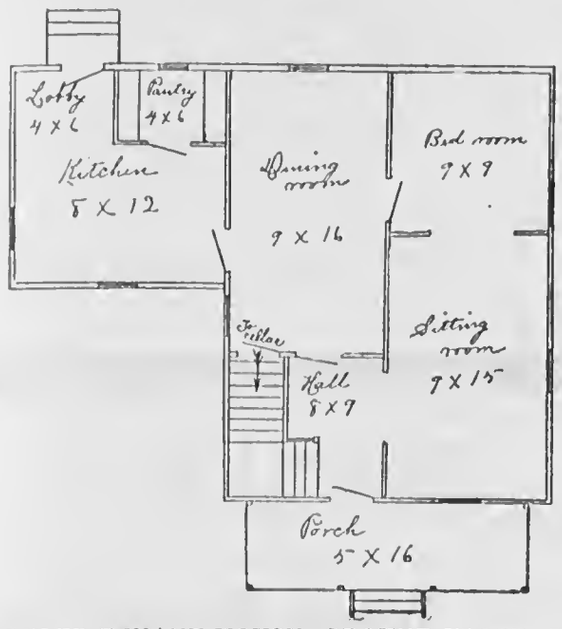
"What else has it done?"

"That ought to be enough, but the trees are becoming more vigorous. You will see whole orchards which now hold their leaves until after heavy frost, where five years ago the trees were bare as poles before frost came. This is due to spraying, which has kept the leaves green and thrifty all through the season. Several years of this have given the old trees new life and vigor. We are satisfied, too, that spraying and cultivation have prevented the off year in our Baldwins. They now bear every year."

THE FARM HAND PROBLEM DISCUSSED.

Another Michigan Farmer Talks.

In your issue of April 13 appears an article from "Michigan Farmer" in regard to the hired-help question. It occurs to me that the $15 per month which he mentions as paying is an uncommonly low price to pay for the labor of competent men. The price is too low, even if the man were boarded, but in this case it seems he boards himself. I should expect ar-



REMODELED TENANT HOUSE—GROUND FLOOR. Fig. 130.

ticles to be missed, and men to take advantage in my absence, and things to go wrong in general, if I hired men who would work for such wages as that; for either the man is incompetent, or he places a fearfully low value upon himself if he will sell his labor for such wages, and in either case I should not want him. If farmers expect to retain the same class of help as gravitate into other lines of business from the farm, then they certainly must pay somewhere near the wages that other lines of business pay. Cheap prices buy cheap goods whether it be in merchandise or in labor, and farmers must wake up to this fact, or their best men will leave them either to obtain homes of their own or sell their labor where it will bring the better price. RAY SESSIONS.

Antrim Co., Mich.

The Hired Man's Side.

In your issue of April 13, you comment on the ideal farm hand. He will never make his appearance during the reign of the present razorback employer. Here in this vicinity a man is expected to work 13 or 14 hours a day in Summer and as much more as his employer can get out of him. A young man here who thoroughly understands the dairy business, the care of stock when sick or well, good milker, understands care and use of horses, handy with tools, who can do almost anything in the jack-carpenter or wheelwright line, who spends rainy days mending harness and doing other repair work, thoroughly reliable everywhere, sober and industrious, asked his employer for a slight raise of salary, no more than other farmers of his class were paying. He was informed that his employer could secure other help at the wages he is now paying. Now, if intelligence is of no use to farmers, why do they ask it, and if they ask it, why should they not be willing to pay for it? The fact is that good working fools are what is wanted, who will work all night or Sunday without comment. A man of intelligence cannot afford to waste his time on a farm at starvation wages when there is such a demand for his services in other lines. J. M. B.

Maybrook, N. Y.

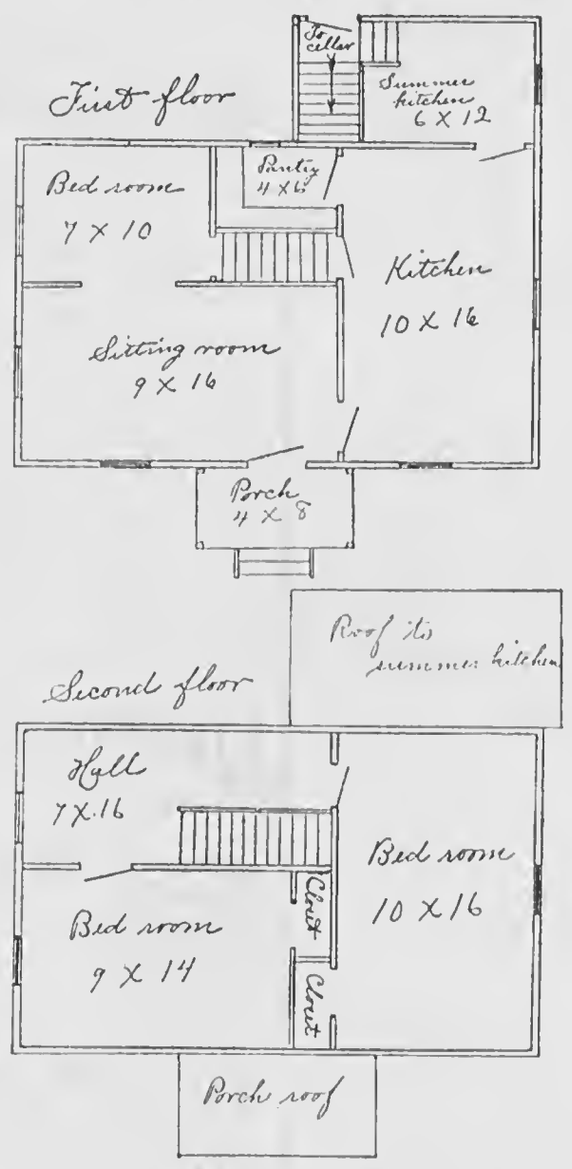
How to Get Help.

I think Michigan Farmer starts right by giving his year man a house and privileges, but he will be a long time getting a really good man for $15 a month who must board himself out of it, no matter how much or how little he works. This is not enough under any circumstances. A man who is the son of a farmer, but has roughed it in working out, said when I read the article that he would expect any man to steal and soldier about as this man seems to if the pay was so small. "I know of a young man," said this man, "who gets $22 and board and washing for nine months a year, and he has a horse to drive whenever he wants it." Certainly $15 a month would not board a man if he had to hire it of some one else, and it would not leave much to support a family on if it was provided by the man's own family. A farmer who, several years ago, found himself without a man, wrote to the Commissioner of Immigration at Castle Garden, New York, and asked for a good man with family, promising him a permanent home if he proved satisfactory. In return the Commissioner sent him a Swede, paid his fare to destination, saw that he had family baggage enough to insure his following it, checked it to destination and sent the check to the farmer. The result appears to have been eminently satisfactory to all concerned. The man "worked in" all right and stuck to his old-world frugal life, so that he steadily accumulated money, and soon he will own his own farm and have it pretty well paid for. It is a neat thing to do, for the country as well as the individual. If the common renter of land, who is now the chief source of impoverished farms, could be handled in that way, there would soon be a vast improvement in the condition of the farming community the country over. JOHN CHAMBERLIN.

Erie Co., N. Y.

Tenant Houses on the Farm.

Very little is said in our rural papers concerning help on the farm. With us, however, it is a matter of no little importance; but the help problem has been solved to our satisfaction; and so pleased are we with our present system of hiring, that we desire to give others the benefit of our experience. We consider it best for all concerned to hire married men, furnishing them house, garden, firewood and milk; or, if preferred, keep a cow for them. I never hire without a written agreement, a copy of which, signed by both parties, is kept by each as a memorandum. Supposing I am to pay $225 per year, I draw up a writing to that effect, adding that it is to be paid monthly, as follows: January and February, $12 each; March and April, $18 each; May, $20; June, $26; July, $30; August and September, $20 each; October, $18; November, $17, and December, $14. Then add whatever I am to furnish, also a clause stating that the hired man is to be present every day at milking time, or furnish a substitute. This plan of varying the monthly payments



TENANT HOUSE—FIRST AND SECOND FLOORS. Fig. 131.

with the seasons is, I think, the safest way for a farmer to hire, as there is not a month in the year when some other might not be hired to do the same work, at the same wages. As a rule, eight hours in the field is as long as we work; and as each man has from eight to 10 cows to milk I consider that long enough. If I am absent at milking time (which seldom occurs) the one who milks my share of the cows gets a quarter for his trouble. There are many farmers who hire one or two men the year around, and always hire single men, at so much per month and board. If you suggest to one of these men that it would be better to hire a married man and let him board himself, he is almost sure to say he "does not doubt it, but cannot afford it." Perhaps he has no house for a hired man and feels that he cannot afford to build, so he goes on in the same old rut, letting his wife cook, bake, wash and iron for his helpers, seldom sitting down to a meal with his family alone, when by a little extra exertion on his part, a neat little cottage might be built and a man hired who perhaps would give much better satisfaction, with more prospect of a long term of service; and when a man has become thoroughly acquainted with a farm and the lines upon which it is managed, his services are worth much more than while he is learning; and on the other hand, the prospect of a permanent position with increase of wages is an incentive to a man to do his best. The two small tenement houses, plans of which are shown in Figs. 130, 131 and 132, cost so little and at the same time are so neat and attractive, comfortable and convenient, that no one need say he cannot afford to build. Fig. 131 is built of hemlock with the exception of the shingles, which are red cedar. Floors of the best hemlock flooring, walls of planed stock lumber, double boarded with building paper between; battened on the outside and finished inside with 4½-cent muslin, which by some, is considered preferable to plaster for walls that are to be papered. The lower rooms are eight feet high, the upper ones seven feet. The cellar, 13x16, is seven feet high. The following shows the cost of building, making no account of my own work, or stones for cellar wall, drawn from our own fields:

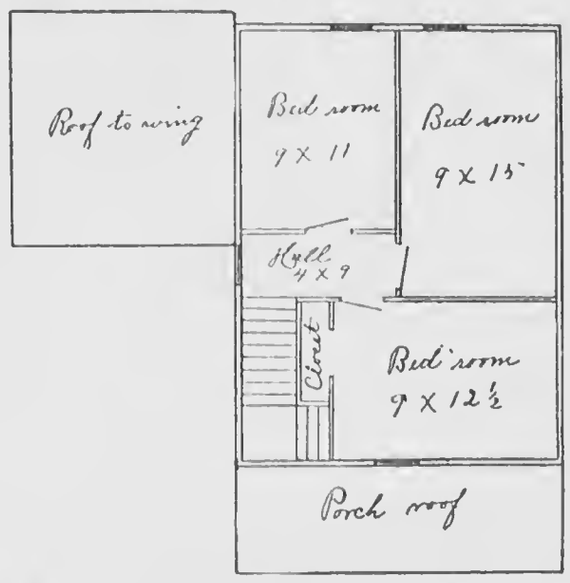
Lumber and shingles	$120.38
Doors and windows	21.95
Brick for chimney	2.80
Lime and sand	3.00
Hardware, building paper and paint for inside	9.18
Muslin	11.25
Carpenters' work	22.80
Masons' work	9.00
Common day labor	14.05
Paint for outside	5.00
Total	$219.41

I am unable to give the exact cost of Fig. 130, as it is an old house remodeled, but feel safe in saying that the difference in the cost of the two houses would not exceed $50. J. S.

Allegany Co., N. Y.

An ex-Farm Hand Talks.

I was interested in the article in THE R. N.-Y. in regard to an ideal farm hand. There are plenty of such men, Americans, too, who might be had if farmers are willing to pay for their services, I will not say as much as they can get as common day laborers, but I will say reasonable pay for the services demanded. I agree with the "year man" that he has not got a "good thing." I have worked on a farm in every State between Maine and Nebraska, taking in Michigan—so I know something about farm hands and farmers, and I have left farming several times to go to work on the railroad. I did not leave the farm for the railroad because I liked that better, nor altogether because of the money. An illustration will show. I was looking for work in Illinois one Spring. I heard of a man who wanted a hand, and called to see him. He wanted a man to work for $18; I wanted $20. We compromised on $19 and the hired man to pay for his washing. That man had nearly 100 head of stock, and kept no hired man in the Winter. When I began work there were more carcasses of cattle lying out in the cornfields, starved and frozen to death, than would have paid the wages of a man at $20 per month for a year. It is unnecessary to say I did not stay with that man long. I left him and went to work at railroading at $50 per month, and sometimes made $25 per week. Board and room cost me about $18 per month, and $2 for washing left me $30 per month without any extras. I should have preferred to work for a good man on a farm for $25 per month, and I am only one of many more of the same mind whom I have known. Then there is another class of farmers with whom I have had some experience. I hired to a man once who laid out work enough to occupy the time of three men and six big horses two years, and wanted me and one darkey with three small mules to do it in one Summer! That is the trouble with the average farmer. They have work enough fully to occupy the time of three good men and teams; then they hire a man for $12 to $18 per month and perhaps only one team, or possibly three horses, on the farm, and they try to do the work by crowding everything from the time that they can see in the morning until it is dark at night. If farmers would use more reason and common sense they would be able to make farming "pay," and we should not hear so much of the cry: "Farming don't pay." I say that a man who does not



REMODELED TENANT HOUSE—SECOND FLOOR. Fig. 132.

make $1,000 profit on 100 acres of tillable land, is not working that 100 acres to the best advantage.

Plymouth Co., Mass. FARM HAND.

R. N.-Y.—We would like to ask "Farm Hand" if he can make any such profit himself!

The Time to Quit.

"At 45 begin to prepare for the time when some younger hand must take the reins. Don't hang on too long," says THE R. N.-Y. on page 257. That depends on how he has lived. If he has taken a lot of whisky and not taken as good care of himself as he has of his horse, it may be so, but if he comes of good stock and has lived right the best 15 years of his life are to come.

A MICHIGAN READER.

R. N.-Y.—We are willing to put that to a vote! Let's hear from the thousands of R. N.-Y. readers who have lived *"right"!* Our idea was that it is well to get out of the harness gracefully before it grows fast to the shoulders!

The Plum Leaf Spot or "Shot-Hole Fungus"

J. H. H., Battle Creek, Mich.—I have an orchard of about 800 plum trees, Lombards and Abundance. Two years ago they were affected with what is known as the shot-hole fungus, the leaves falling in August from the Lombard trees, for a distance of from six inches to two feet from the trunks. The first plums that ripened were those near the ends of the limbs, and were very small. There was little growth of wood. Last season almost all of the leaves fell from the trees, so that it became necessary to shake the plums, which were thickly set, from the trees during the first part of August, when the plums were not more than half grown. The trees grew less than the previous year, and partially leaved and blossomed durng September. The growth of wood had a speckled russet appearance. Is this disease fatal? If not, how can we avoid the recurrence of last year's experience? The trees are nine to 10 years, from one to two-year nursery stock, being on good heavy two to three-foot sandy-clay soil, with gravelly subsoil. The trees have borne four or five crops of fancy plums. The leaves did not fall from the Abundance trees, but the fungus seemed to eat holes through the leaves. The trees have been sprayed with the Bordeaux Mixture each year, save one, since they began to bear.

ANS.—The "shot-hole disease" is a popular name which is often given to the spotting of the leaves of plum, cherry and apricot by the attacks of a fungus, the Cylindrosporium padi. For certain technical reasons it seems best to call this trouble the leaf-spot disease of plum, cherry and apricot. It may cause even more serious loss than that described in the above letter. One fruit grower in western New York reports that one season it was so abundant that many of the plum trees lost a large part of their leaves in August before the fruit ripened. The ripening of the fruit by such trees when they were barren of leaves, together with the loss of the foliage, caused them to enter the Winter in such weakened and ill-prepared condition that many of them were winter-killed. While the disease does not often cause so great destruction as this, yet it doubtless does greater damage than most fruit growers imagine. When the conditions are favorable to its development and spread, nearly all the leaves may be attacked and eventually a large percentage of them drop on this account. Often the diseased spots break away from the healthy leaf-tissue, and drop out, leaving holes with clean-cut edges; often circular in outline. In this way the appearance is produced which has given rise to the name "shot-hole disease." A shot-hole appearance, however, cannot be regarded as positive proof of the work of the leaf-spot fungus above mentioned. Duggar has shown, for example, that treatment with improperly-prepared spray mixtures and also that other causes may produce a shot-hole appearance similar to that caused by the attacks of the leaf-spot fungus. Sometimes certain insects eat holes in the plum leaves, which an inexperienced observer might take as evidence of the work of the fungus.

The first appearance of a leaf-spot which would ordinarily be noticed is found in discolored spots one-sixteenth of an inch in diameter or even less. At this stage, especially on plum and cherry leaves, the spots may have a reddish-tinged border. They may soon increase in size to one-eighth of an inch, or more, in diameter and the color may change to dark brown with pale center. The diseased and discolored tissue may remain in the leaf, but usually it drops out and leaves the "shot-holes" referred to above. The holes formed in the leaf are not always circular, but when several spots coalesce into one, or when conditions are extremely favorable to the rapid spread of the disease, large irregular-shaped patches may drop from the leaf and give it a ragged, worm-eaten appearance. The infested leaves frequently turn yellow and drop prematurely, so that it is not uncommon to see twigs of the current season's growth nearly or quite leafless in August or later. The tree may lose nearly all of its leaves before September. A considerable loss may be seen as early as July, but usually the loss of foliage is not serious before August or September. *Treatment with Bordeaux Mixture is recommended.* Carefully conducted experiments have proved that this leaf-spot disease may be controlled by timely use of properly-prepared Bordeaux Mixture. It has also been shown that a weak mixture, in which but one pound of copper sulphate is used to 11 gallons of the Mixture, is efficient in controlling the disease if properly prepared and applied, and if the treatments are made at the right time. In some seasons two treatments are most economical, but generally at least three treatments should be made. The first should be given about 10 days after the blossoms fall, but not later than June 1. The second treatment should be made from two to three weeks later. The time may be varied according to the apparent necessities of the case. The third treatment should be made about three weeks after the second. Be sure that the Bordeaux Mixture is properly made. Follow minutely the directions as given by the United States Department of Agriculture, or by some of the agricultural experiment stations.

A word of caution may be added. It may not be generally understood by fruit growers that the leaves of the stone fruits are much more liable to injury from applications of arsenical compounds than are those of either the apple, pear or quince. Even Bordeaux Mixture alone may injure peach foliage, although it apparently does no harm to plum foliage. But plum foliage may be seriously injured by Paris-green and by other arsenical compounds. It is best, therefore, not to use arsenical poisons in spraying plums unless such treatment is demanded by imperative necessity. [Prof.] S. A. BEACH.

Geneva, N. Y.

How to Raise Water.

D. H. W., Kerrmoor, Pa.—In getting a water supply for house and barn, which would be the cheaper in the end, to pump water a distance of 50 rods, with an elevation or rise of 100 feet, or drill a well on the hill above the buildings, the depth of which would be 100 to 150 feet? In the former instance the source would be a spring. In both plans a windmill would be used to do the pumping.

ANS.—We do not understand all the conditions, but judging from our own experience we should prefer the drilled well and windmill on the hill. We think this would insure a more constant supply of water. We have more wind on our hills than in the valley. By putting a tank on the hill you will have pressure enough to give you a good water supply in house and barn.

A Four Years' Rotation.

J. E. D. (No Address).—Will you give a four-years' rotation of crops? Land now in pasture and worn-out meadow.

ANS.—In deciding upon any rotation it is necessary to understand what crops can be sold to advantage and how much money is available for fertilizers. The Rhode Island Experiment Station (Kingston) in Bulletin 74, advocates the following rotation—potatoes, rye, clover. The rye is sown after potato digging, and the clover seed added in the Spring. Wheat might be used in place of the rye and corn planted in the clover sod making four years instead of three. This rotation gave a fair profit in Rhode Island. We cannot, of course, name the best rotation for you without knowing more about what you wish to sell and how much labor and money you wish to spend.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

DRY SEASON EXPERIENCES.

Plow Early and Cultivate Late.

Last Spring I planted 500 peach trees, very late, on land plowed very early and tilled until trees were set. One of my neighbors set 350 trees two weeks before I did, and on land plowed immediately before the trees were planted. I lost eight trees out of the 500, and he lost over 50 out of his 350. We experienced very dry weather this year, and my crops were cut below what they would have been under favorable circumstances. I used the "weeder" on my wheat and oats, sugar beets, beans, potatoes and corn, and find it valuable in securing a surface mulch. My Syracuse lever spring-tooth drag does my digging and mellowing, and a Daisy wheeled cultivator, which is also a spring-tooth implement, does my cultivation. In potato culture I made great use of a home-made coverer and hiller when potatoes are young, to be followed in a few days by weeder. Although I have no underdrains as yet, I drain the surface very thoroughly, always leaving open drains, made every night, when I am plowing, and re-opened after tillage, and also study to plow, to benefit the surface of the field by filling hollows and making water courses from them. I noticed a piece of beans planted June 13 last on land plowed early in Spring. They germinated (appeared at surface) in seven days. Another piece planted same day on land just plowed and fitted to receive the crop did not show above the ground for over 24 days, and many never came. A rain broke the drought, or they would have been there yet. You cannot say too much in favor of early plowing or surface mulching by tillage. My land is mostly sand, and I commence plowing before frost is all out (on sod) and continue in as great haste as possible until land for my Spring crops is all turned over. I consider it a great weed-killing device or process, to limit meadows to one year, and two mowings at that. C. H. P.

Sodus, N. Y.

Here is strong argument in favor of early Spring plowing which lowers the water table; but which must be followed by persistent surface cultivation to hold the moisture. Of course this practice would not apply to heavy clays, which must be cautiously handled to prevent caking.

The Budding Farmer.

I decided some time ago to be a farmer. I like the Reading Course very much. I think the last lesson is a dandy. I am going to put the seeds in the flannel and try it. My brother and I have a flock of geese together. We sold two for $1 aplece, and would like to sell the rest for that much. I have $6.35 and my brother has $5.86 (he is eight years old.) We are going to invest it in black raspberry roots. When they get to bearing I think I shall be large enough to take care of them. I am most 11 years old now. I like to split wood and milk and hunt the eggs, but I don't like to fill the wood box or clean the stables. I like to hoe in the garden, so you see I will enjoy taking care of our berry roots. We have five horses and 21 cows and 60 chickens. We have a silo and like it very much. I hope you will write again some time.

Watkins, N. Y. R. G.

I am very glad to get your newsy letter. You are going to be a farmer. That's right! Many men are not fitted for farming; they are better suited for keeping store, arguing, or teaching other men how to be good. The best farmers are those who like their work. Of course there is not any farmer who likes all parts of his work equally well. I can remember when I was of your opinion regarding the filling of the wood box. It wasn't a nice job and the sticks were heavy, but then I used to stop and think how comfortable it was in the evening when the stove was piping hot, while the wind went whistling by outside. You are furnishing comfort for all. That is the thought we ought to have in mind when we are filling the wood box. I hope you will be successful in growing your blackcap raspberries. Be careful to secure one-year-old plants, unless you can get the tips at a nearby nursery and set them out yourself quickly; otherwise there is a chance of losing many of them in the operation. You know that the blackcap multiplies in a curious way; the tips of the cane bend down and take root in the soil. These are called tip plants. If you plant these they should not be planted very deep; not more than two inches of soil should be put on top. If they are set lower than this they are likely to smother.

MACHINES FOR PLUM CURCULIO.

Several Subscribers.—What machines are used in fighting the Plum curculio, and how are they used?

The little picture (Fig. 133 shows the Johnson curculio machine, which, we understand, is a success. It is like a big inverted umbrella on wheels. There is an opening at the side, so that it can be

THE JOHNSON CURCULIO MACHINE. Fig. 133.

pushed up under the tree. One man wheels the machine under the tree, then jars the tree—and bags the curculio. The following notes are from persons who have used the machine successfully:

We commence to use the machine soon after the blossoms have fallen, and continue using it once a day on each tree until the plum pit gets too hard for the curculio to penetrate, unless the weather becomes very warm, which makes the insect more active, and then we use it twice a day to each tree. I would not try to grow plums in a commercial way without this machine. My experience tells me that this insect cannot be destroyed by spraying. B. F. KEAN.

Geneva, N. Y.

The machine being mounted on light, easy-running wheels makes the work of jarring and catching the curculios mere play compared with the old slow way of jarring on sheets. It could be improved by using oilcloth for covering in place of muslin, as the curculio would more readily roll into the receptacle below, but as it is we find it in every way practical, and a great labor-saving device to plum growers. We have grown the plum 28 years, and were overrun with curculio from the start, but by persistent jarring every day that weather would permit while they are the most numerous we have usually raised good crops, but we must be watchful. Some seasons it is comparatively easy to raise a crop, and the next we may have to fight from the time they are out of the blossom until the fruit is nearly ripe. One brood follows another so rapidly that there is no let up, but we always gauge our jarring by the number of insects caught. J. K. SOUTHARD.

Ottawa Co., O.

We used to catch the insects with an old-fashioned machine, which had to be carried about by hand. The Johnson catcher being on wheels is a great improvement in this respect, as one man can do more work with it than two with the old style, and much easier too. I think they should be made to fold up more easily than they do, as the large-sized machines are difficult to wheel through gateways, and if in going from one orchard to another there is occasion to travel on the road it is liable to frighten horses. The best time to jar the plum trees is in the morning or on cool cloudy days, as the insects are much more easily caught, being more stupid. We sweep them and the plums, etc., which drop, into the box which is made for the purpose; if the day is bright this would need to be done quite often for fear the curculios would fly away. If they are not very plentiful we often mash them on the canvas, which saves sweeping. The number of times the trees would need jarring depends very much on how thick the insects are. If quite plentiful I think every other day would do for two or three weeks, or until they begin to get scarce. Sometimes if the trees are loaded with fruit and there are not many curculios, a few jarrings will be sufficient. We often have to thin the plums afterwards, but then if we did not jar at all there might be too many of the plums stung. If necessary the machine can be used for peaches, too, or any fruit that is stung, if the trees are not too large. We pour hot water on the insects and plums to destroy them; often take a tight sack along to the field to empty box into.

Tompkins Co., N. Y. EDWARD WOOD.

How and When to Feed Ducklings.

On page 234, March 30, F. E. W. gives some good directions for raising and feeding young ducks. I wish he would also tell us how often to feed them. We tried a few last year, and out of about 20 hatched only raised two. Ought we to feed two, three, five or more times in a day?

Liberty, N. Y. M. K.

Ducklings, when first hatched, would best be fed every two hours, or five times a day, just what they will eat up clean in a reasonable length of time. If any is left take it away till next time. After they are about a week old, extend the intervals so as to feed four times a day. If incubator birds, they will thrive best and be str nger if left in the machine two days after the hatch is cleaned up, and not fed till placed in the brooder. When grit is not convenient sand answers nicely. Have a dish of it always accessible to the babies and stir about two tablespoonfuls into the feed. A good combination drinking vessel for small ducklings is a roast-beef and a tomato can. Punch a hole in the latter 1½ inch from the open end; fill the can with water and place the dish over it, then reverse it. The water fills and feeds out to the ducklings as required; it avoids their getting wet and chilled, or clogged-up nostrils. For the first week or two the water should be tepid, otherwise either chicks or ducklings are liable to have cramps. F. E. W.

Chazy, N. Y.

Why Not
Preserve Wheat and Rye Straw Straight Bound in Bundles?
Please your customers by saving barnroom and ease of handling straw. We make a machine that we guarantee to thrash wheat perfectly clean and not bruise or break the straw, that will bind it again in bundles. The same machine thrashes rye and preserves the straw, straight, bound in bundles, and is also changed in 15 minutes to a spike-tooth oat and wheat thrasher Send for Catalogue B. Free

NOTES FROM THE RURAL GROUNDS

DAMP AND CHILLY WEATHER.—It has never been the purpose of the writer of these notes to say more about local weather conditions than is needed to explain trial results. The cold dry winds of February have already been mentioned on page 212, and the fear of injury to evergreens and exposed new plantings has been fully justified. Many beautiful groups and specimens of the more sensitive Thujas and Retinosporas on neighboring grounds are so injured as to be worthless, and the mortality among Rhododendrons is greater than for the last 15 years, though the temperature did not at any time reach zero by at least four degrees. The several species of Euonymus have lost most of their leaves, even where well protected, and exposed plants of the Cherry laurel, Prunus laurocerasus, and the dainty little Garland flower, Daphne Cneorum, are apparently killed to the ground. Since the beginning of March, however, there has been a constant succession of storms preceded and followed by days of cloudy weather with chilling winds and fogs from the sea. This slow and halting approach of Spring is distinctly beneficial to exposed grass and grain lands, which are recuperating in an unexpected degree from the Winter's damage. Even the blackened stems of half-hardy roses and tender blackberries are regaining color in many instances, and pushing buds at points seemingly dead a few weeks ago. Fruit buds of all kinds appear to be in good condition, but are naturally coming on at a slow rate under the cool conditions. The prospects for a local crop of the various fruits is very good, the only danger greatly feared being a recurrence of the cold rains in the blooming period.

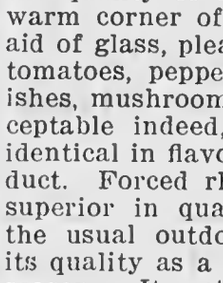
A GRAND NEW HARDY ROSE.—Since the introduction of the vigorous and hardy Rosa rugosa from Japan and North China persistent attempts have been made to create, by hybridizing with other species and highly-improved garden roses, new varieties combining its special qualities and peculiarly handsome foliage with greater perfection and freedom of bloom, and increased range of coloring. Considering the innumerable crosses that have been made by patient experimenters on both continents the net results are really very meager. Mme. Georges Bruant is the offspring of a Tea rose pollenized by the white-flowered Rugosa, and was the first useful hybrid sent out. It is a very thrifty grower and produces when well established immense clusters of large semi-double white flowers with a pleasing odor. It is constantly growing in favor in the Northern and Prairie States on account of its hardiness and reliability. The late Mr. Carman, of THE R. N.-Y., next produced the popular Agnes Emily Carman, by crossing the common pink Rugosa with Harrison's Yellow. The unexpected result was a large double brilliant crimson bloom of much the shade of Gen. Jacqueminot. The plant is particularly rugged and hardy, and the foliage really exceeds the typical Rugosa in beauty. It blooms very freely, and continues almost all Summer. Mme. Charles Frederick Worth has the famous Paul Neyron for the pollen parent, and is in many respects the finest of the colored Rugosa hybrids on the Rural Grounds. It is strong and stately in growth, and the blooms are more double, and have a better finish than its competitors, but the season is scarcely as long. Souvenir de Pierre Leperdrieux, sometimes sold as Souvenir de Yeddo, has proved the most continuous bloomer of any yet tried, producing clusters of double bright red flowers until late Fall, which are abundantly followed by fair-sized fruits. All other Rugosa hybrids are sterile with us. Blanc Double de Coubert is another double white-flowered variety, looking more like the species than a hybrid. The blooms are quite double, pure white and possess a delightful fragrance. It was introduced from France in 1894, its parentage being Rugosa and Kamschatka roses.

The writer has been growing Rugosa hybrids since 1893, and has bloomed many hundreds of interesting crosses, only two or three developing characteristics of horticultural value. This is about the experience of all hybridizers who have used the Rugosas extensively. So variable and inferior are the usual results that it has been supposed Rosa rugosa is not an actual botanical species, but a natural hybrid between certain Asiatic wild roses. Its varieties reproduce themselves very readily from seed, but diverge widely when pollen from other sources is used. The finest Rugosa hybrid yet developed on the Rural Grounds is shown on first page, Fig. 128, under the name of New Century. It is now being disseminated by the Conard & Jones Co., West Grove, Pa., the growers of the Ruby Queen rose which is now in the hands of many R. N.-Y. readers. New Century was raised from seeds of the hybrid Polyantha rose, Clothilde Soupert, the male parent being the single white Rugosa. It was only secured by persistent effort to effect a cross that should theoretically produce good results. More than 500 pollenizations were made before the first sound seeds were produced, and many subsequent trials have since been required to secure others. New Century sends up a forest of strong thorny canes, three or four feet high, when established, each topped with a cluster of five to 11 large, perfectly double blossoms with a bright carmine rose center, shading to white or rose pink at the edges. The fragrance is particularly agreeable, being almost identical to that of the woodland wild rose, R. lucida. The strong, erect bushes are clothed with handsome Rugosa-like foliage, but of a lighter green tint. The picture was made from a careful painting of a cluster, large enough to fill a peck measure. The artist, however, for pictorial effect, has concealed the single stem from which all the blooms spring in the representation of a vase. This specimen was grown in the highlands of Tennessee on good soil and was the most artistic natural cluster of roses the writer has ever seen. The hardiness of New Century seems to be entirely established, as it has been grown in several widely-separated localities four years without the slightest Winter protection, and has never been injured, even by a temperature of 26 degrees below zero. If well fertilized it is almost continually in bloom, but must be cut back well in the Spring and again in July to promote the formation of new shoots. There is little doubt that Rugosa hybrids are destined to wide popularity when their merits become more fully known, especially where the so-called hardy garden roses are commonly winterkilled. The Canadian Experimental Farm at Ottawa classes the various Rugosa hybrids as "half-hardy" in that severe climate, in distinction to such entirely hardy varieties as the Rugosas proper, Persian Yellow, etc. By half-hardy is meant that tender late growths are often killed, but matured wood is seldom injured. A perfectly hardy plant should preserve its terminal buds like a currant or gooseberry through any stress of temperature. Practically, we have found moderate winter-killing of more benefit than injury, as it necessitates closer pruning than might be given if all the growth remained intact. We would counsel those who plant roses of the New Century type to put them in rich, moist soil when possible, and away from buildings so that the erect and robust habit may be preserved. While blooms may be produced the next season after planting, the bushes will not show their full development until three or four years have passed, but are apparently good for a life-time if not allowed to starve.

WINTER DELICACIES.—Of all the Winter delicacies we have been able to grow the quality of the rhubarb forced in a warm corner of the cellar, without the aid of glass, pleases the palate best. The tomatoes, peppers, beans, lettuce, radishes, mushrooms and cress are very acceptable indeed, but they are nearly identical in flavor with the Summer product. Forced rhubarb is immeasurably superior in quality and appearance to the usual outdoor growth, apart from its quality as a desirable novelty at the season. It retains a delightful pink color when cooked, and the flavor is a delicate and refreshing fruit acid without a trace of astringency. The plants in the cold cellar are just beginning to grow, and will scarcely develop more than 10 days earlier than the garden clump. In the heated cellar (soil temperature at 55 degrees) five plants have given a constant supply for a small table since early February, and are still sending up new stalks. W. V. F.

Mr. J. A. Gardner, of Colchester, Conn., writes: "I know that my potato vines on which Bowker's 'Boxal' was used keep green long after others were dead." —*Adv.*

The Finest Spray



A perfect fog-like mist is thrown out by
RIPPLEY'S
Compressed Air Sprayer
and
Whitewashing Machine,
or throws a continuous stream 30 ft. heigh, as desired. Never scorches foliage. Make solution go farther than any other sprayer. Great for whitewashing. Holds 5 gallons. Can't burst. Salary to reliable men. Address
MARTIN WAHL Rochester N. Y.

Hope Farm Notes

FARM NOTES.—Hope Farm has a clean face at least. Rain! Rain! Rain! That has been the programme all through April. When the rain did not fall a cold, raw wind came out of the northwest, licked the moisture out of the soil and rubbed it down our backs. Between rains Charlie plowed and sowed the oats, while Hugh and Brent planted peach trees. We must be at least 10 days behind the average season. . . . . The Crimson clover has been strangely backward this year. In former years at this time I have known it to be six inches high by May 1, but this year it has hardly started. On two fields I gave it up as lost, as I could not see it from the lane. When I came to walk over the field I found it covered with little clover plants. Give them 50 hours of warm sunshine and how they will jump! . . . . I sometimes read advice from people who tell us to roll down the grass and grain early in the Spring. That would be a foolish thing to do this year, for every time a horse put his foot into the soft ground he would up-root far more grass than the roller would pack down. There is no use adding to the flood of rain by crying over it. Every tear weighs a ton by the time it hits the damp ground. . . . . Some of our farmers planted potatoes at about the usual time—April 15—regardless of the condition of the soil. They like to get the seed out of the way. I think it is safer spread out in the sun above ground rather than down in the cold wet soil. I don't think we gain anything by planting in soil that is not ready. In a season like this we get the most benefit from dusting the seed with sulphur before planting. I am sure that it keeps the seed from rotting, and I am satisfied that it helps keep off the scab. It is also my belief that the sulphur gives a stronger plant—less likely to be affected by blight—though the scientific men say that there is nothing in this. . . . . The coal stove in the house was taken out on April 20. Usually it pays to keep the fires going longer than this, but we are quite comfortable from the big wood stove. . . . . The hens walk about like soaked feather pillows, yet they laid 474 eggs in the first 20 days of April. These eggs are strong, too. Out of 220 put into the incubator, 198 were fertile. I expect to set about 1,500 plants of early cabbage grown and transplanted in Florida and sent to New Jersey by express. I wish to see how these southern plants, grown entirely out of doors, compare with the northern hotbed candidates.

WHAT IS THE TRUTH?—I have had the following note from a good friend who evidently thought from something said in THE R. N.-Y. that first-class farm hands were easily to be found:

"I want to say further that having been brought up from a child with THE R. N.-Y. we have always taken its word as law and gospel, and you must not print anything that you cannot stand by or that is misleading in any way, for we country people are prone to believe everything we read."

Every person who puts thoughts into print should understand that he assumes a great responsibility. Our friend says that country people are prone to believe everything they read. I should want to edit that statement somewhat. I find people very anxious to believe the truths that run right along with their own beliefs or desires. I have known these same people to reject and cry out at other truths which rubbed them the wrong way. We all know the story of the blind men who went to see an elephant. One got hold of his tail and was ready to swear that he was like a rope. Another struck his leg and knew he was like a tree, and so on. It is much the same way with most of us in describing an object or a method. We see it from one point of view, and it is almost impossible not to put a little of our own estimate or belief into it. That is the way a good many so-called "big stories" get into print. The writer, without knowing it, lets his imagination run, and the result is that he tells, without meaning to do so, not just what he saw, but what undoubtedly *would be* if the plans were all worked out as they should be. Our friend is right. There never should be a line written for THE R. N.-Y. by one who knows that truth can come and lash him away from his statements.

KICKERS.—I have that last statement right in mind when I say that in my opinion Julia can kick harder and quicker than any cow in this country. Julia is a black cow, and Genevieve is her brown daughter. I bought them late in February of a man who wanted to sell out. He said he gave Julia her name because she was born in July. Genevieve was his idea of a January birthmark. Following out this line of thought I don't see but that Julia's calf, born in April, should be named Ape! Genevieve is a gentle little thing, but the conduct of her mother is "something scandalous." Kick! Charlie is a truthful man, and he insists that she can kick with all four feet tied! She is a good cow, and able to give a large mess of milk, but one would about as soon milk a tiger. I am afraid her heels will punch holes through too many good resolutions. The most successful milkers thus far have been her son and grandson—the two calves. We will let her make veal of these two youngsters, and then get other calves to follow, if possible. We will sell Julia or make beef of her next Fall. I have been forced to do some "kicking" myself in my day—the Madame also will say that many of her rights are kicked-over wrongs—but Julia certainly goes up head as a star. "That's another of your bargains!" murmurs the Madame. When I bought her she was like a lamb. How could I know she was only waiting for a chance to kick my head off?

THE HAPPY MAN.—I cannot say what put it into my mind, but I spent several hours of a wet Sunday thinking over this question, "Who is the happy man?" The soak and drip of the rain were enough to drive a fellow crazy with sad memories, or else make him forget his stiff knees and dance for joy that he had a dry home that he could call his own. Nature's tears meant laughter for the grass and grain. *"Who is the happy man?"* I tried to analyze the feelings of all the Hope Farm folks, and of friends whose lives have been opened to me. I couldn't find one over 15 years old who can be said to be fully happy! Many of them ought to be, and some think they are, but there is a knothole of character somewhere, though often painted over. This one is haunted by the memory of some old-time mistake. Another feels a dead place in his make-up where some noble or helpful impulse was undeveloped. That one is under the lash of poverty or ill-health. This one feels that in spite of all his efforts to earn true happiness evil tendencies master him at times and undo his best. Still another has seen the work of long, patient and self-denying years trampled under foot by carelessness or ingratitude. *Who is the happy man?* I run over all the friends I can think of, and see that they are all carrying or shirking their share of the world's great load of trouble. The carriers are happier than the shirkers—there's no doubt about that, but there is no happy *man*—though, thank the Lord, there are millions of happy children. The man who comes nearest to happiness is he who hangs longest to his childhood, and when that becomes too dim to hold lives it over again with his children. As I sit struggling with these useless thoughts the little Bud climbs on my knee. She studies the mournful drip of the rain and asks slowly: "Father, are you glad it's raining?" There comes to my mind the absurdity of being anything else but glad—the futility of growling about the things we are powerless to help, and I put myself on record as glad to make the best of wet or dry, and by so doing, for the moment at least, I find—the happy man!

H. W. C.

OHIO FARM NOTES.—Since I have commenced feeding the roof off the shed I have come to the conclusion that there is less waste than there would have been from the same amount of fodder shocked in the best possible way and allowed to stand till this time. I have sown 10 acres of clover sod to barley and Alfalfa; 1½ bushel of former and 16 pounds of the latter per acre. It is a costly experiment, yet if it wins it will pay me a heavy return in furnishing hay for lamb feeding. The only drawback now is sufficient storage room under roof for my clover hay and Alfalfa, if I am so fortunate as to succeed with the latter. However, before I tear down my barns and build greater, I must make a cheaper improvement in the shape of a wind pump, and from now till Fall I shall give a good deal of time to the study of wind-pump literature. About 500 lambs will have gone through my yards by the time the feeding is wound up from the first to the middle of May.

ROSS ENSILAGE CUTTERS
Furnished with BLOWER or CARRIER, as desired.
GUARANTEED to be the BEST.
E. W. Ross Co., Springfield, O.
Send for Catalogue No. 44
51 Years on the Market.

THE WHEEL OF TIME
for all time is the
Metal Wheel.
We make them in all sizes and varieties, TO FIT ANY AXLE. Any height, any width of tire desired. Our wheels are either direct or stagger spoke. Can FIT YOUR WAGON perfectly without change.
NO BREAKING DOWN.
No drying out. No resetting tires. Cheap because they endure. Send for catalogue and prices. Free upon request.
Electric Wheel Co.
Box 88 Quincy, Ills.

OSGOOD SCALES
What is a guarantee on a scale worth? Nothing if not backed by a reputable, practical, solid scale concern, whose goods have stood the test of time, and who are personally interested in the scales shipped out under *their own brand*. *Osgood* stamped on a beam is a guarantee of faithful, practical workmanship—and much more, which we want you to know. Write for our catalogue. Don't wait—we save you money. OSGOOD SCALE CO.,
(Established 1865.) 103 Central St., Binghamton, N. Y.

BUGGIES AND HARNESS
HARNESS $4.15
THIS $50 TOP BUGGY $28.50
YOU CAN BUY FROM US AT FACTORY PRICES
BUGGIES, PHAETONS, SURREYS, WAGONS, ALL KINDS OF HARNESS.
We will sell direct to you a vehicle or harness as cheap as dealers buy their goods in car-load lots. Don't pay profits to middlemen. Our work is all high-grade, correct style, and elegantly finished.
SEND FOR FREE CATALOGUE SHOWING LARGEST LINE VEHICLES AND HARNESS IN THE UNITED STATES.
All Work Guaranteed and Shipped on Approval.

SUBSCRIPTION: ONE DOLLAR A YEAR.

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs.

"A SQUARE DEAL."

We believe that every advertisement in this paper is backed by a responsible person. But to make doubly sure we will make good any loss to paid subscribers sustained by trusting any deliberate swindler advertising in our columns, and any such swindler will be publicly exposed. We protect subscribers against rogues, but we do not guarantee to adjust trifling differences between subscribers and honest, responsible advertisers. Neither will we be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent us within one month of the time of the transaction, and you must have mentioned THE RURAL NEW-YORKER when writing the advertiser.

Name and address of sender, and what the remittance is for, should appear in every letter.
Remittances may be made in money order, express order, personal check or bank draft.
THE RURAL NEW-YORKER,
409 Pearl Street, New York.

SATURDAY, MAY 4, 1901

THERE seems to be strong ground for the belief that the poison of the honey bee's sting may be used to prevent or cure rheumatism in humans. This was suggested several years ago but was not regarded seriously. Careful investigation seems to show that there are possibilities in the treatment. We once saw a rheumatic farmer mow into a bumblebee's nest. If ability to run fast is any indication the cure was instantaneous.

*

THE annual call for information about skunk farming has begun. Day after day we receive letters from persons who have heard of successful skunk farms, and who want a share of the great profits to be found in the skunk's society. We have traced down dozens of these farms, and never found one that paid. We say, therefore, to one and all, that those who embark in skunk farming are sure to be skunked—that is, they will never make a point except to be pointed at by their neighbors as brothers to the skunk.

*

WE recently met a man who is buying his farm at the rate of two per cent per year. According to the terms of sale, he is to pay $2,500 for the farm in 50 annual payments of $50 each. He has the privilege of paying the whole at any time he is able to do so. The former owner was a large land owner who believes that in this way he can obtain fair prices for his land and also give deserving men a chance to become freeholders. If more of the land-rich would meet the land-poor in this way—what a world we would have!

*

THOSE who read the articles by D. R. Pease on using lime and sulphur for Pear blight must remember that he does not pretend to have found a "sure cure." His experiments were satisfactory—that is, the blight was checked. Did the sulphur help? It would seem so, but the only way to make sure is for many growers to try the same thing and observe results. We hope that hundreds of our readers will try the lime and sulphur and report results. The scientific men do not see much hope for this sulphur remedy. Still, we advise a trial of it.

*

ACCORDING to a bulletin recently issued by the National Live Stock Association, the stockmen are determined to conduct an active campaign against the Grout bill on its next appearance in Congress, and this will be the most important business brought before the Association when it meets at Chicago the first week in December. With such powerful interests conducting a determined campaign against the bill, it would be very unwise for dairy farmers to cease their efforts in its favor. Persistent agitation is needed in the interests of the cow, to offset that made by strong organizations who would neglect her for her brother the steer.

*

WHY is the man who works under cover any better than he who works under the open sky? Why should the townsman consider himself superior to the farmer? In some way certain people have come to think that he who stands in a dusty shop, or sits behind a desk or counter, is of a higher type than the farmer who works with his feet in the soil. Strange, isn't it, that the man who crawls off and narrows himself down to the brick and stone of the town should think that he is better or nobler than when he trod the rough hills! Think of the man who has brushed the last speck of soil from his clothes and his character, presuming to step above the man on the farm who works in direct partnership with God! The thing seems preposterous, and yet some farmers help make this sentiment by acting as though they were ashamed of their calling. The business of farming is dignified only by farmers themselves.

*

THE farmer's wife may lay down the law as to what her household shall eat and how they shall eat it. She generally suits her people. The farmer must not think that he can lay down the same law for those who buy his food. That is another thing. There is so much food sent to market that the buyer has the option, and the farmer, or some one else, must meet his demands. It is true that some customers do not really know the best food when they see it. They use prejudice instead of judgment in buying. It will cost money to remove that prejudice, but it would prove a good investment!

*

A READER in a southern State asks the following question:

I have charge of a large dairy and have had a large experience in a practical way, and a natural love for stock. I am 28 years of age. Would you advise me to leave a position that pays me $360 a year and board to take a course in a dairy school?

That is a good job to leave for any uncertainty. A man who can earn such wages for one man can do it for another. If he can make that amount of money without scientific knowledge he can doubtless make more than that with an education. While it is a risky thing to give general advice about change of occupation, we would, were we in this young man's position, attempt to master the science of dairy husbandry.

*

REPORTS indicate a movement of people from the East to the West this year. It appears that hundreds of people in the Mississippi Valley are moving to the Pacific coast—thinking to better their conditions. Some of them, too, are restless by nature, and demand a change of home every few years. We call public attention to the following letter, which shows what some of these immigrants may expect to find at their journey's end:

This land has been homesteaded years ago, improvements were made, buildings and fences put up, fruit trees set out, etc., and during his five years of residence the owner found that the land is worthless except for the timber. He sells the logs to a sawmill, and will now sell the land for a song. Hundreds of such farms have been abandoned. I find that certain parties have a plan to get possession of this land for almost nothing, go to the East and Middle West, and exchange it for land, cattle, stocks of goods, or anything, as what they get in exchange is almost clear profit. When the immigrant arrives at his ranch, his means are perhaps exhausted, and he has to begin life over again.

There are without doubt good opportunities in the Far West for many people. We would put no obstacle in the way of any man who wants to go there. We went there to live years ago—and came back again. We would warn our friends, however, not to exchange farm and stock for a "ranch" about which they know nothing. Far better stay where you are and try to make a new start.

*

WHAT a blessing it would be for the Southern States if southern farmers would draw "the color line" on yellow oleo. No section of the country so sadly needs the society and salary of the dairy cow as the Gulf States. Yet the great bulk of the supporters of oleo came from that part of the country. Can the southern oleo men "make it unanimous"? Not by a good deal. Here is a letter from one of our readers—a Georgia cow man:

Keep up the fight against oleo. Georgia dairymen are with you, if our representatives are not, but we are going to talk with them next election time.

That is one of the most hopeful signs from the awakening South that we have seen. We are glad to see that Georgia cow men are not cowards. Think what would happen to the State of Georgia if her dairy interests were fully developed! Here is a table that will bear study:

State.	Population.	No. of cows.	Value of cows.
Georgia	2,216,331	285,431	$6,836,072
Vermont	343,641	268,886	8,577,463
Indiana	2,516,462	605,855	20,447,606
Michigan	2,420,982	463,698	15,162,925
Wisconsin	2,069,042	1,003,321	33,711,586
Iowa	2,231,853	1,263,283	44,088,577
Minnesota	1,751,394	672,540	21,285,891
Kansas	1,470,495	707,675	22,999,438

Georgia and Iowa are about equal in population, yet Iowa supports nearly 1,000,000 more cows, worth $37,000,000 more than the milch cows of Georgia. The cows on the rough hills of Vermont are worth $1,700,000 more than their sisters on the sunny slopes of Georgia. Give Georgia one good milch cow for each two inhabitants, and let them be well fed and cared for, and the State will receive greater benefit than would be the case if the cash value of every Georgia slave set free at the close of the Civil War was returned to the former owner! In view of these things is it not astonishing that southern Congressmen will join hands with the oleo men whose apparent aim is to kill off the cow?

*

ON page 286 we were told how a Pennsylvania farmer improved a hard, shallow clay loam soil by sowing Cowhorn turnip seed in the standing corn. We have been flooded with letters from readers who ask all sorts of questions about this. The turnip is not an ideal crop for green manuring. Still, it adds a large amount of vegetable matter to the soil. This vegetable matter opens up the hard-packed soil, increases the bacterial action—gives it "life"—in fact, is just what such soils need. The deep-growing root also breaks up the subsoil, deepens the tillable earth and brings fertility to the surface. We have no doubt that a crop of these turnips will increase the power of the poor soil to produce other crops in far greater proportion than we could expect from the actual fertility which they contain. They may actually fit the land, so that it will grow clover or cow peas. Where a man can afford to buy fertilizers we do not consider it good economy to use a manurial crop alone. Turnips, like buckwheat, can utilize crude forms of plant food, making them over into available material for corn, wheat or potatoes. We would, if possible, use fertilizer of some sort when growing a crop to be turned under.

*

BREVITIES.

How dear to our heart is the bright silver dollar,
When some kind subscriber presents it to view;
The liberty head without necktie or collar,
We long for the bush where the pretty thing grew.
The wide-spreading eagle, the arrows below it,
The stars and the words with the glory they tell,
The coin of our fathers, we're glad that we've got it,
For some time or other, 'twill come in right well;
The spread-eagle dollar, the star-spangled dollar,
The old silver dollar we all love so well.
—Credit Lost.

* * *

The word of some men who are faultless in grammar
Wouldn't sell for five cents if put under the hammer,
While others who knock all the grammars to smash
Are known to be worth their face value in cash.
Still, that is no argument why anyone
Should kick out "I did" and put tongue to "I done."

* * *

Let us once more our tale rehearse;
This time we frame it in a verse.
Do not mix lime, I beg you, men,
Into organic nitrogen.
For nitrogen's a shaky scamp,
And ever ready to decamp.
"Affinities" but lightly hold,
A chap so fickle and so bold,
And lime will come with burning hand
To cut the all too fragile band
That holds organic nitrogen
In harness for the good of men.
Wait till you get him in the soil;
Then let him out and make him toil.
But if you value cash or care
Don't set him free in open air.

* * *

LOOSE statements get men into tight places.

IT'S the boiled-down article that "burns on."

THE growth some people need is to grow small.

THE sensational reporter is the write man in the wrong place.

ASK the hog if the grass sward is not mightier than the pen!

LISTEN to the *mocking* bird—in other words, the lying cackle of the robber hen.

THE people who but live to stuff and eat will surely call their later years a cheat.

TRUTH will put rubber into a man's conviction. The more people "jump on him" the harder they bounce back.

THE Canadians exported 10,187,906 dozens of eggs last year, while our own countrymen sent abroad but 5,910,162 dozens.

DURING the past year American exports of butter decreased $120,442, while exports of oleo oil increased $1,320,197.

THIS very rain that drives us out of the field is a God-send to the dairy farmers whose meadows have been brown so long.

IF this wet weather continue there will be less need than usual for soiling crops this Summer. Still, we shall plan for a dry August.

WE use the formalin solution by pouring it over the oats and then raking them into a damp pile. It is also used the same as for potatoes—by dipping the oats down into it.

LORD ROBERTS says the American wagons are the best sent to Africa, but that the American mules do not equal those from India. The mules probably sympathize with the Boers!

SCARLET fever rages in a New Hampshire town, and to prevent its spread all money passing through the local bank is sterilized. Some people put their money through what is known as "a hot time," without destroying its germ power for evil.

RUSSIA seems likely to become a formidable rival to butter-producing countries, the exports for the first 10 months of 1900 being 37,729,200 pounds. The principal increase of export is the butter product of Siberia, for which butter trains equipped with refrigerating apparatus have been employed to transport the goods to the ports for shipment.

"We state what we sell, And sell more than we state."

More than Ten Thousand Government Tests have been made of Bowker's Fertilizers in the past thirty years of samples taken in the open market, and they show that these goods have always contained more plant food than was guaranteed by the makers.

They have been used by more than One Hundred Thousand practical farmers every year on every variety of crop and soil with splendid success.

They are made of the best materials which the markets of the world afford, and are compounded on scientific principles.

They are soluble, active, sure.

They enrich the earth and the men who till it.

YOU are invited to join the great army of Bowker patrons and grow such crops as you have never grown before.

Send for Circular **M** relating to fertilizers; also Circular **24** relating to spraying and the insurance of crops. It will be worth your while.

BOWKER FERTILIZER COMPANY
(INDEPENDENT)

BOSTON NEW YORK CINCINNATI

Woman and Home

From Day to Day.

This is somebody's birthday,
Just as sure as fate;
Some little boy is six years old,
Some little girl is eight.
Some little boy is three to-day,
Some little girl thirteen,
Some little twins are exactly two—
Two apiece, I mean.

Some one is eating his birthday cake
And laughing over the plums;
Some one is counting her birthday dolls
On all her fingers and thumbs.
Some one is bouncing his birthday ball
Or winding her birthday watch,
Some one is not too wise or tall
For birthday butter-scotch.

Think of the beautiful birthday books,
Think of the birthday cheer,
Think of the birthday happiness
Every day in the year!
Every day in the year, my dear,
Every day we're alive,
Some happy child is one or two
Or three or four or five.

—Youth's Companion.

*

THE deep drawers often provided in a closet to hold household linen, are difficult to move when filled, and in place of this a convenient closet has deep shelves, fitted with covers which let down. The covers seen on some book shelves, which roll up and down like spring blinds, would be suited for this.

*

POPPING corn seems a very easy process, but there is a right and a wrong way of doing it. To get the best results, pour over it enough cold water thoroughly to wet it, allowing this, of course, to drain away; then shake it on the top of the stove long enough to be thoroughly heated before it is moved to a warmer place. The steam of the wetting softens the shell, and when the corn begins to pop all bursts open at once, leaving no hard core.

*

SOME small boys are so perpetually in mischief that what is left of their conscience may accuse them unnecessarily, like that of the small William described below:

"Now, boys," said the patient Sunday school teacher, "surely some one of you can tell me who carried off the gates of Gaza. Speak up, William."

"I never touched 'em!" said the indignant William, with a suspicion of tears in his youthful voice. "I don't see why folks always think when things get carried off that I've had something to do with it!"

*

EXCEEDING flounciness is one of the characteristics of the thin Summer dresses seen in the large stores, some of them having from three to five flounces. They are preferably flare or ripple flounces, but in many cases additional fullness is given to them by shirring or pleats. Where pleats are used, they are often put in clusters at each seam of the skirt. Rather an odd style was an inverted box pleat at the center front and center back of a graduated flare flounce, and no other pleats, the material being a heavy linen.

*

INNUMERABLE small buttons are seen among the dress trimmings, and some of them have little danglers or tags hanging from them, giving them a very dressed-up appearance. They are used extensively on silk waists in gilt, and in black or white silk. Sometimes both black and white buttons are used on the same waist; for example, a gown of figured foulard, black and red upon a white gown, had a vest trimmed with white silk buttons, while upon the edges of the foulard were rows of black buttons. Combinations of black and white, or black, white and red, are very fashionable, though the early Spring saw the usual outbreak of pale gray, which we see every year. Many women seem to feel that their earliest Spring costume must preferably be delicate gray or dove color, no matter whether it is becoming or not, and such gowns looked strangely unseasonable during the boisterous wind and rain that brought March weather into the first half of April.

*

IN discussing the desirability of moving from the city to take up life on a farm THE R. N.-Y. has often referred to the fact that restlessness on the farm chiefly results from feminine dissatisfaction with farm life. In other words, farm life is largely what the women make it. This fact makes the agricultural college the best place for giving

3684-Work Gown.
32 to 40 in. bust.

higher education to ambitious farm girls, as well as boys, and we may look for great results from the system. Any education that makes a girl grow away from the farm, when there is every probability that she must always make her home upon one, is a grave mistake. The domestic-science course at an agricultural college must elevate the student's appreciation of everyday things, while bringing her in closer sympathy with the life on the farm.

*

FOR a consistently republican country we are just a little given to unnecessary titles. The Hope Farm man tells us that in a certain small southern town he visited, after modestly disclaiming any right to be addressed as colonel, professor or doctor, the entire population united in calling him judge, and he was obliged to live up to the dignity of this distinction during his visit. He says that his claim to this distinction rested upon the fact that he acted as umpire in a baseball game, to the entire satisfaction of both teams. The following item from Leslie's Weekly illustrates this title-giving custom:

"Second Cousin Philenda's youngest daughter, Mary Ella, is married," Farmer Hornbeak annnounced upon his return from the village. "Niece Theodosia stopped me as I was drivin' along an' told me to let you know that she'd just got a letter from Okonk, where Philenda's folks live, sayin' that Mary Ella was married week before last to Professor—er—er—Somebody—I don't exactly recall what the name was."

"A professor?" returned Mrs. Hornbeak, in pleased tone. "I guess, then, that she's made a good match of it an' got a man of education an' social standin', if so be that he's a professor. I'm real glad 'tis so, too."

"Wa-al, I don't know," said the old man, shrewdly. "That depends a good deal, 'cordin' to my way of thinkin', on what variety of the species he belongs to, so to say. Theodosia didn't tell me, an' I forgot to ask, whether he is a dancin' master, a corn doctor, a piano tuner, a prize fighter, a hoss physician, a layer-on-of-hands, a balloonatic, a seventh son of a seventh son, a sword swallower, a phrenologist, a bicycle rider, a magician or an elastic-skin man."

The Rural Patterns.

A comfortable working gown need not necessarily be an unbecoming one, and the design illustrated will recommend itself to those who wish to look neat and trim while at their household tasks. Preferably it is made of washable stuff, such as percale, in order that it may be laundered and made fresh at need; but flannelette is entirely suitable when greater warmth is required, as is any inexpensive lightweight woolen material. With the gown should be worn the simplest of neckties and belts. The waist is in spencer style, and differs from a shirt waist in extending to the waist line only. The back fits smoothly across the shoulders and is drawn down at the waist. The fronts are gathered at the neck and again at the waist line, and the entire lower edge of the waist is attached to the upper edge of the belt. The sleeves are in bishop style and are finished with pointed cuff bands that lap over at the seam and hook invisibly into place. At the neck is a shapely standing collar. The waist is closed at the front with buttons and buttonholes. The skirt is cut in five gores and falls only to the floor. It fits smoothly across the front and about the hips, and is arranged in gathers at the back. The placket is made at the left front seam, where it closes invisibly, and the upper edge of the skirt is attached to the lower edge of the belt, the left half of the front gore being attached to the extra portion and hooked over into place. To cut this gown for a woman of medium size 7½ yards of material 27 inches wide, seven yards 32 inches wide, or six yards 44 inches wide, will be required. The pattern No. 3684 is cut in sizes for a 32, 34, 36, 38, 40 and 42-inch bust measure. Price 10 cents from this office.

Eton jackets are unquestionably the favorites this Spring. The jaunty little model shown includes all the latest fea-

3794 Eton Jacket,
32 to 42 in. bust.

tures, and can either be made with the vest and kaiser collar or without either, in the mess-coat style, as preferred. The original is of broadcloth in a shade of castor, with the vest white, closed with cut steel buttons, the collar white overlaid with appliqué in black, and makes part of a costume; but the same design is suited to all suiting materials, wool and linen, and to the general wrap. For the latter use, it is preferably black cloth, cheviot, taffeta or peau de soie, with the vest of embroidery or some such tone as castor, pastel, tan or gray. Made without the vest and collar it is simply stitched and worn plain, or with the addition of a collar of batiste or Russian lace, and becomes a most satisfactory light wrap for wear over all gowns. The back is seamless and absolutely smooth. The fronts are fitted with single darts and joined to the back by means of under-arm gores that are well shaped and aid in producing the perfect fit. The narrow vest is joined to the fronts at the darts, and the collar is attached to the neck and back and sides, flaring as it reaches the front. The sleeves are two-seamed and flare becomingly over the hands. To cut this jacket for a woman of medium size 2¾ yards of material 21 inches wide, two yards 32 inches wide, 1½ yard 44 inches wide, or 1⅜ yard 50 inches wide will be required, with ¾ yard in any width for vest and collar facings. The pattern, No. 3794 is cut in sizes for a 32, 34, 36, 38, 40 and 42-inch bust measure. Price 10 cents from this office.

Preparing Codfish.

When a codfish or a fraction of one is brought into the house it is a saving of time and patience to pick it up at once; that is, remove the bones and skin, and store it in empty fruit cans or a jar, then it is ready to use at a moment's notice and there is no drying up hard, as is always the case when it is simply hung up. Dry bread may be broken up tolerably fine and the same amount of shredded codfish added to it, the whole covered with water; butter and pepper may be added, and as it comes to a boil an egg stirred in briskly makes an agreeable addition.

Another simple form of picked codfish is thus prepared: To a teacupful of codfish picked up and freshened add two teacupfuls of sweet milk, and set on the stove in a porcelain or other suitable dish. Take two tablespoonfuls of butter and rub into it about as much flour, and when the milk comes to a boil thicken with it, and stir well. One boil completes it. AUNT RACHEL.

THE world loves a true and noble woman more than the greatest beauty that ever lived or the most brilliant intellect. Within the memory of every one there are noble, womanly lives, which have been dearer and better to us than the most brilliant women of history.—A. S. Atkinson.

Safe Pure Sure

Babbitt's 1776 Soap Powder

Guaranteed by 64 years of continuous Babbitt success — tested by the public and never found wanting. Absolutely all right — cannot injure anything — does its work and does it well.

Rural Recipes.

Russian Jelly.—Soak half a box of gelatine in a gill of cold water for 10 minutes, and pour it into a pint of boiling water with a cupful of sugar and one of orange and lemon juice mixed up in the proportion of one-fourth orange and three-fourths lemon. Strain and set in a cold place to thicken enough to be whipped with an egg-beater to a stiff froth. Wet a mold with cold water, put in a little of the jelly, then a layer of candied fruit, sliced fresh fruit or preserves, more jelly and more fruit until the mold is full. Serve with whipped cream.

Rhubarb with Figs.—Wash a half-pound of bag or pulled figs and cook in boiling water to cover until the water is nearly absorbed. Skin and cut a pound of rhubarb in one-inch pieces. Put a layer in a baking dish, sprinkle with sugar, add a layer of figs, repeat until all is used; put in a quarter of a cupful of hot water and bake in a slow oven until the rhubarb is soft. Dates or raisins may be used with the rhubarb in the same manner. Serve with plain or whipped cream.

Coffee Cream Cake.—Mix three teaspoonfuls of baking powder with three cupfuls of flour. Cream one-half cupful of butter with one cupful of sugar, beat the yolks of four eggs, add a second cupful of sugar, and when light and creamy combine with the butter mixture. Add one cupful of strong coffee and then the flour mixture, and last the whites of the eggs beaten stiff. Bake in two shallow pans. When done, split carefully and put in a filling of coffee cream. Sweeten one cupful of thick cream and flavor it to taste with black coffee. Chill and whip it stiff with a wire spoon; then spread half-inch layer on one of the cakes. Put little slivers of apple jelly over the cream; cover with the other half of the cake and sprinkle powdered sugar over the top. Cut in long, narrow slices. Lemon filling may be substituted for the other layer if preferred.

Kornlet Roughrider.—Two cupfuls of finely chopped cooked meat, any kind; season with a scant teaspoonful of salt, one saltspoonful of pepper, one-fourth teaspoonful celery salt, one tablespoonful of grated onion, add one beaten egg, one tablespoonful of melted butter, two tablespoonfuls cracker crumbs. Mix this thoroughly together. Take 1½ cupful of kornlet, two cupfuls of bread crumbs, saltspoonful of salt, dash of pepper and one-fourth cupful of milk; mix thoroughly. Butter well a small granite dish, line the bottom and sides quite thick with the kornlet; pack in the meat, cover the top closely with kornlet, spread a teaspoonful of soft butter over this and steam 45 minutes; then put in the oven to brown about 15 minutes. Loosen it around the sides of the dish, turn it out upon a hot platter and pour tomato sauce over it. Serve at once.

Boston Tea Cakes.—Beat two eggs in a teacup, fill the cup with sweet milk, turn into a bowl with one cupful of sugar, 10 even teaspoonfuls of melted butter, 1¾ cupful of flour and two teaspoonfuls of baking powder. This is the most reliable, easily made and accommodating of cakes. Dellcious baked in layers and spread with jam or cream. May be baked in a loaf or small patty pans. Serve warm with tea.

Gooseberry Catchup.—It is well to make a note of this recipe now, before gooseberries are in season. Five pounds of fruit, three pounds of sugar, 1½ quart of vinegar, one tablespoonful of cloves, three tablespoonfuls of cinnamon, two tablespoonfuls of allspice. Wash the berries, put them in a porcelain stewpan, mash them well, add the other ingredients and boil until thick. Seal while hot.

MOTHERS.—Be sure to use "Mrs. Winslow's Soothing Syrup" for your children while Teething. It is the Best.—*Adv.*

Living in a Cage.

Grandma Rosemary went last Summer to her native village to visit her niece, who a year before had married a farmer in the neighborhood.

They went one day to take tea with a friend of Mrs. Rosemary's girlhood. As they came near the door grandma said: "That old house has not altered in the last 20 years! There are the same closed green blinds at the parlor windows, and the same tin pails sunning on the kitchen bench, and the same Dahlias and sunflowers in the yard. There is Serena in the door, a little leaner and grayer, but otherwise just the same."

She found no alteration inside the house, either. Serena lived alone. She gave them the same kind of biscuit and veal cakes and honey which grandma remembered when she was young. They sat in the bare, clean parlor, with the blinds closed. The sofa, the table, the chairs stood in the same places as when Serena was a child. She talked of but two or three things—crops and the weather and the neighbors, topics so old that they had a musty flavor.

When the visitors were on their way home, grandma drew a long breath. "Twenty years ago," she said, emphatically, "Serena Nutt was talking of the yield of corn in that field, and of the sharpness in business of the Nutts, and of the best way to make succotash, precisely as she did to-day! Her mind goes round and round in the same little circle, like a squirrel in his wheel. She doesn't know that there is a world outside of this village!"

She paused a moment, and then said: "It is no credit to me that I am not like her. My husband was an editor, and my sons were in business and went about the world a good deal, so windows opened into my life on every side. When we sat down to breakfast the men talked of the great events of the day, as reflected in the newspapers, or of an expedition to the North Pole, or of some new book or some discovery in science. I am like David. I thank God that He has 'set my feet in a large room.'"

"He has not set me in a large room," said her niece, gravely, 'but in a very small one. My husband works hard on the farm and I in the house. There is danger that I shall be shut in with as few ideas as Serena has. It is the great danger in farm and village life. But what can one do?"

"Open windows and doors in your little room," said Mrs. Rosemary, promptly. "Take one or two of the best magazines, and read them. Keep up with the action of the great outside world in every way possible to you. Write to your old acquaintances. Don't spend your money in new-fashioned gowns or parlor furniture, but in books, magazines, and above all in little journeys with your husband. It is only by measuring yourself with strangers that you can get your true measure."—Youth's Companion.

Household Remedies.

We read that Mrs. Carrie Nation looks like a woman who could "teach Sunday school, bake bread and make mustard plasters," and we can imagine the little self-approving smile to which the busy reporter treated himself after thus deftly touching off the three saving graces. Did the shadow of some dear soul who had ministered unto him in his time of need, flit across his mental horizon as he paused for the hundredth part of a second for words that would exactly describe the impression made upon him by this startling woman? Had he just recovered from the grip and had he found out, by experience, that the warm proposition of the home physician was after all the most consoling thing in the world? A mustard plaster consoling? Yes, I mean just that. I will, however, admit that there are irritating mustard plasters, just as there are consoling women and irritating women. Little dabs of plasters, made by tearing off a piece of muslin, say 4x8 inches, smearing it with a tablespoonful of sloppy mustard, then folding over, making a four-inch square—this is an irritating non-quieting kind. But tear off a generous piece of old thin muslin about 6x12 inches, on one-half of it put two even tablespoonfuls of dry mustard and one tablespoonful of white flour, mix lightly and spread evenly over the cloth, then sprinkle with hot vinegar or water until the surface is quite damp, fold over the other half of the muslin, turn up the edges slightly and apply wherever needed—I assure you it will warm you up admirably! In cases of nervous sick headache a plaster of this kind on the stomach will prove very soothing, and induce sleep. After an hour the plaster may be removed from the stomach and placed on the back between the shoulder blades and kept there until the strength has gone out of it. Thin-skinned patients insist upon having soft muslin cloths well smeared with lard—it is more cooling than vaseline—placed over the mustard's pathway, others do not care to be bothered with anything of the kind—and they also survive!

A mustard plaster on the chest will loosen up a cough wonderfully. Also a mustard foot-bath, hot as can be endured taken before going to bed, accompanied by a good hot drink of lemonade, will give relief. A hot-water bag, wrapped in flannel or a well-heated flat iron treated in the same way, should always be placed in a grip sufferer's bed as a foot-warmer. "Keep the head cool and the feet warm" is the good nurse's saving charm. In cases that show symptoms of pneumonia, having sharp pains in the region of the lungs, hot onion poultices put on one after the other until the patient is relieved are more efficacious than mustard plasters. The onions should be sliced and fried in lard until soft, then put into a little woolen bag—a leg of an old merino stocking sewn up at one end is handy. Place this over the seat of pain just as hot as the patient can bear it, and have another bag ready to change with as soon as the first grows lukewarm. Keep this treatment up until the patient is relieved. This simple remedy is often prescribed by physicians, and we have tried it so often on home folks that we know, beyond the shadow of a doubt, that it is good. When the pain has ceased apply greased cloths and cover with a good thick layer of cotton batting. This should be worn several days as a protection against further cold, the greased cloth being changed daily. In country places it takes so much time to get a doctor that it would seem to be the duty of a good house-mother to know what to do in cases of emergency. Yet so many women yield to a feeling of helplessness and fright and will not venture to do a thing for a sick person until the doctor arrives, and expressly orders this or that done. In the meantime the moments seem like long hours to the sufferer. DOCIA DYKENS.

THE greatest difficulties are found where least expected; the greatest successes come from where they are least sought.—Ivan Panin.

THE world wants men who are saved from secret faults. The world can put on an outside goodness and go very far in uprightness and morality, and it expects that a Christian shall go beyond it and be free from secret faults. A little crack will spoil the ring of the coin. —Mark Guy Pearse.

WE have nothing further to do when the scroll of events is unrolled than to accept them as being for the best. If we could take all things as ordained and for the best, we should indeed be conquerors of the world. Nothing has ever happened to man so bad as he had anticipated it to be. If we would be quiet under our troubles they would not be so painful to bear.—Gen. Gordon.

THE principal requirements of a good paint are: *covering capacity, durability, appearance and economy.* Pure White Lead and Pure Linseed Oil is the only paint that fulfils these requirements.

A building painted with Pure White Lead will look better and last longer than if painted with any other material, and the first cost is less; and as its covering capacity and durability are much greater, it is by far the most economical.

For any color or shade required, use NATIONAL LEAD COMPANY'S Pure White Lead Tinting Colors. Pamphlet sent free upon application.

National Lead Co., 100 William Street, New York.

THE Philadelphia North American relates the following cure for hiccoughs: "The doctors tried ether and various other remedies without success. As a last resort they placed a piece of ice on the patient's abdomen when he did not expect it. The man was so frightened that he stopped hiccoughing at once."

BUSINESS BITS.

GEO. STRONG, of Smithtown Branch, N. Y., says he is using a two-horse-power Mietz & Weiss kerosene engine for pumping water to a height of 90 feet, and can cut cabbage at the same time and have power to spare. Address A. Mietz, 128 Mott St., New York City, for catalogue and prices.

W. J. CAPRON, V. S., writes to Lawrence-Williams Co., Cleveland, O., as follows: "I read your advertisement about Gombault's Caustic Balsam and have tried it for the last year in a great many cases and found it perfect. Its use in my practice has become so much increased that I would like to know what you will charge me for it by the dozen."

WE desire to say to people who contemplate buying low-down steel wheels that the grooved-tire wheels, made by Havana Metal Wheel Co., Havana, Ill., are giving the very best satisfaction. They make the flat tires as well as the grooved, and know that the flat tires do not last as long or give as good satisfaction as the grooved-tire wheels. Get their prices when buying.

WE frequently have advertisements of the Animal World, which offer pets of all kinds free, and which have been cut from other papers, sent us with the request whether they are reliable. The publisher of this paper has been recently arrested and held in $2,500 bond to answer charges of fraud. We have never heard of anyone getting pets or anything else for money sent them. The previous good standing of the paper accounts for the advertisements appearing in some papers which do not knowingly accept such advertisements.

THE Elkhart Carriage and Harness Co., Elkhart, Ind., make claim to being the largest manufacturers of vehicles and harness in the world, selling to the consumer exclusively. Having decided long ago that the public would much prefer to deal direct with the manufacturer, the man who made the goods, if the people but could be convinced that they were getting the best goods at the lowest procurable price, the Elkhart people inaugurated their present system. The results of 28 years of experience in carriage building are given in their free illustrated catalogue.

"SOLUBLE AND SURE."—Perhaps you never stopped to think what a bag of fertilizer represents. The deserts of South America provide nitrate of soda, the great city factory sulphate of ammonia, the animals that do our work or provide our meat give bone, blood and tankage; the mines of the South and of Germany give phosphoric acid and potash, while the ocean is scoured to furnish fish scrap. We hold a handful of the fertilizer, and realize how two continents and a dozen localities are represented. We are not speaking of a cheap and clumsy mixture of acid rock and kainit with a faint smell of tankage, but of high-grade complete goods such as are sold by the Bowker Fertilizer Co., of Boston, Mass. These fertilizers are said to be soluble and sure! Who say so? Farmers who have bought them for the past 30 years, and crops that have talked in that universal language—money. This is but the first chapter in the story. It is continued in the catalogue issued by the Bowker Company, and all should read it.

ILLINOIS GRASS NOTES.—I am entirely out of grass ground. For some reason for the last three years it has been impossible to get a catch from Spring-sown grass seed. I sowed twice with oats and failed; then at suggestion of a friend I tried barley, as it is said the oat stubble is likely to burn out the young grass during our usual hot dry weather in August and September, but I failed with that. One of my neighbors had the same trouble with Spring-sown seed; sowed in the Fall and has a fair stand. Possibly Fall-sown seed has a chance to get a firmer grip, so can withstand a probable drought. Cow peas have proved a bonanza to those who have failed with grass. Have any of the dairymen found that cow peas fed to cows made the butter strong? A. M. C.

Bunker Hill, Ill.

The Cold commonly described as "deep-seated," with pain and soreness in the breast, difficulty of breathing, and all that, yields quickly to Dr. D. Jayne's Expectorant.—*Adv.*

Guide to the Pan-American.

Exquisite blending of soft harmonious colors has given to the Pan-American Exposition the name of the Rainbow City. Just as beautiful in its blending tints is the handsome little guide book issued by the Lackawanna Railroad, giving information that every Pan-American visitor is anxious to have. Write for one, inclosing 4 cents in postage stamps to T. W. Lee, General Passenger Agent, New York.—*Adv.*

Market Briefs.

PICKED UP HERE AND THERE.

SCARECROW FOR MOTHS.—The ordinary moth balls sold at drug stores are such vile-smelling things that people dislike to use them in packing away garments that they consider of much value. It is well known that the odor of Red cedar is distasteful to moths, and putting blocks of this wood in packages of clothing that are to be stored is a quite effective protection. A convenient form of this was seen in the form of Red cedar shavings, cut up in about the same shape as excelsior, pressed in blocks a little larger than the ordinary building brick, retailing at 10 cents. These blocks may be torn in pieces and sprinkled into the packages to be stored. The odor is not disagreeable and soon disappears when the garments are taken out to air. The best protection for furs is cold storage, and the warehouses in this city do a large business in this line every season.

POTATO CONDITIONS.—The general tone of the market is weaker than for some time, and the prices given are rather high for average lots. This does not apply to selected seed potatoes, which, if anything, are higher. People often complain of the difference between the prices of seed and table stock, though there may be no noticeable difference in the tubers. No doubt there is some inconsistency in this, and the needs of planters may be taken undue advantage of. Yet it must be remembered that few farmers keep their potatoes pure, the great bulk that is received in the markets for consumption being mixed stock. Those who take pains to keep the tubers of different varieties separate, and know that they have not been frosted so as to injure the sprouts, have a right to expect a little extra for their trouble. Where a farmer is raising and storing a number of varieties, often much alike in shape and color, it is no easy task to keep them separate through the various handlings that are necessary before they are disposed of in Spring. Sweet potatoes are firm and a trifle higher than last week.

CHERRIES AND GRAPES.—This is quite a combination of early and late fruit, yet to a limited extent they are both on sale in this market. The cherries are from California. A few boxes have been received by express, and there will be regular shipments every week from this time on. The first lots sold at wholesale for from 25 to 40 cents per pound. They were rather small and inferior. The large hotels are always after these odd and extra-early fruits chiefly to give their tables an air of luxury, which is supposed to please the class of people to whom they cater. The native grapes now offered are Catawbas and the last of the cold-storage stock. Nearly all of the larger fruit stores have the baskets holding about three pounds, and retailing at 25 to 35 cents. As might be expected, the grapes are badly decayed or withered, and in a whole basket but few are found that retain their natural flavor. Like the cherries, they are bought because of their scarcity. There are plenty of Malaga grapes remaining in the markets. Their tough skin, hard pulp and habit of sticking tightly to the stem, make them long-lived, but so far as quality goes, they are poor substitutes for our native grapes. W. W. H.

SCRAPS.

WHERE can I get the Vineland bush sweet potato? W. T. K.

Write to F. S. Newcomb, Vineland, N. J.

IN response to L. F. P., Gleasondale, Mass., there is much evidence to show the Worden-Seckel pear is worth a careful trial, despite its hyphenated name.

A READER who does not give his name wishes the address of B. H. Hite, who last year wrote an article for THE R. N.-Y. on methods of preserving eggs. Prof. Hite's address is Morgantown, W. Va. He is the chemist at the West Virginia Experiment Station.

IOWA CLOVER SEEDING.—Timothy seed has been sown as early as January and given an excellent stand and a heavy crop. The usual time of sowing clover, however, is during the month of March, when the seed is put on while the ground is covered with a light snow that will remain only a few days, the thawing of the snow providing sufficient moisture to carry the seed into the soil and put it in good condition for germination when the growing season opens. I can see but little, if any, advantage in sowing earlier than March. Prior to that time the ground is not usually in good condition. Sometimes there will be deep snow drifted over some portions of the field, and other portions may be bare and exposed to the winds. It is better to allow the sunshine of early Spring to remove these drifts and sow the seed on top of the light snow later in the season. These are of frequent occurrence in this locality during the month of March.

Iowa Ex. Station. C. F. CURTISS.

BERCKMANS BROS. write that they have planted 31,000 peach trees at Mayfield, Hancock Co., Ga. In a year they will have 50,000 plum and peach trees in their orchard.

CURING HAMS.—Your answer to the inquiry of B. G., page 193, as to how to keep smoked hams through the Summer to preserve them from the attacks of insects, is hardly satisfactory. I have found the following a sure preventive if done before the warm weather begins: Carefully wrap paper around the hams—old newspapers will answer. Then take a fair quality of domestic and wrap over the paper, sewing in place. Make a thick whitewash—water and lime—and immerse the cloth-covered ham in the wash. When thoroughly dry, tie a string to the neck of the ham and hang in smokehouse or other place. This I have never known to fail when done before insects gain an entrance to the meat. R. W. C.

Bowling Green, Ky.

CALIFORNIA STRAWBERRIES.—You advise thorough cultivating of strawberries. That is good as far as it goes, but not here. I have one-quarter of an acre, planted three years, and only worked the first year. Of course, the weeds were kept out last year. We had 500 cases, 15 buckets to the case, or 15 pounds. If there is any better crop than that they are not in this part of the country. We picked some March 1 this year, and can pick some any time of the year. We commence to pick in April, and pick until Christmas. They are what is called the Dollar berry. There is no better berry in this part of the country. It will ship to New York if wanted. W. R. G.

Placer Co., Cal.

SHEET FOR LEAVES.—There is one article that I find handy about the place. Take some grain bags, do not rip them up the back, but turn them inside out, start the thread at the bottom end, pull the thread out and you have a small sheet; give the "Bud" five or 10 cents to sew four of these sheets together, using the thread that came out of the bags and a darning needle. The result is a good-sized sheet. If you wish to get some leaves, rake together a big pile of them, spread the sheet close to the pile, and rake the leaves into the sheet, standing on it and treading down the leaves. When it is full tie the opposite corners together, and you put them where you want them. I find these sheets handy to carry bedding into the hen coops. I don't fancy leaves for bedding unless one has a box stall or something to keep them from spreading all over the floor; there is nothing any wetter than a wet leaf. V. E. H.

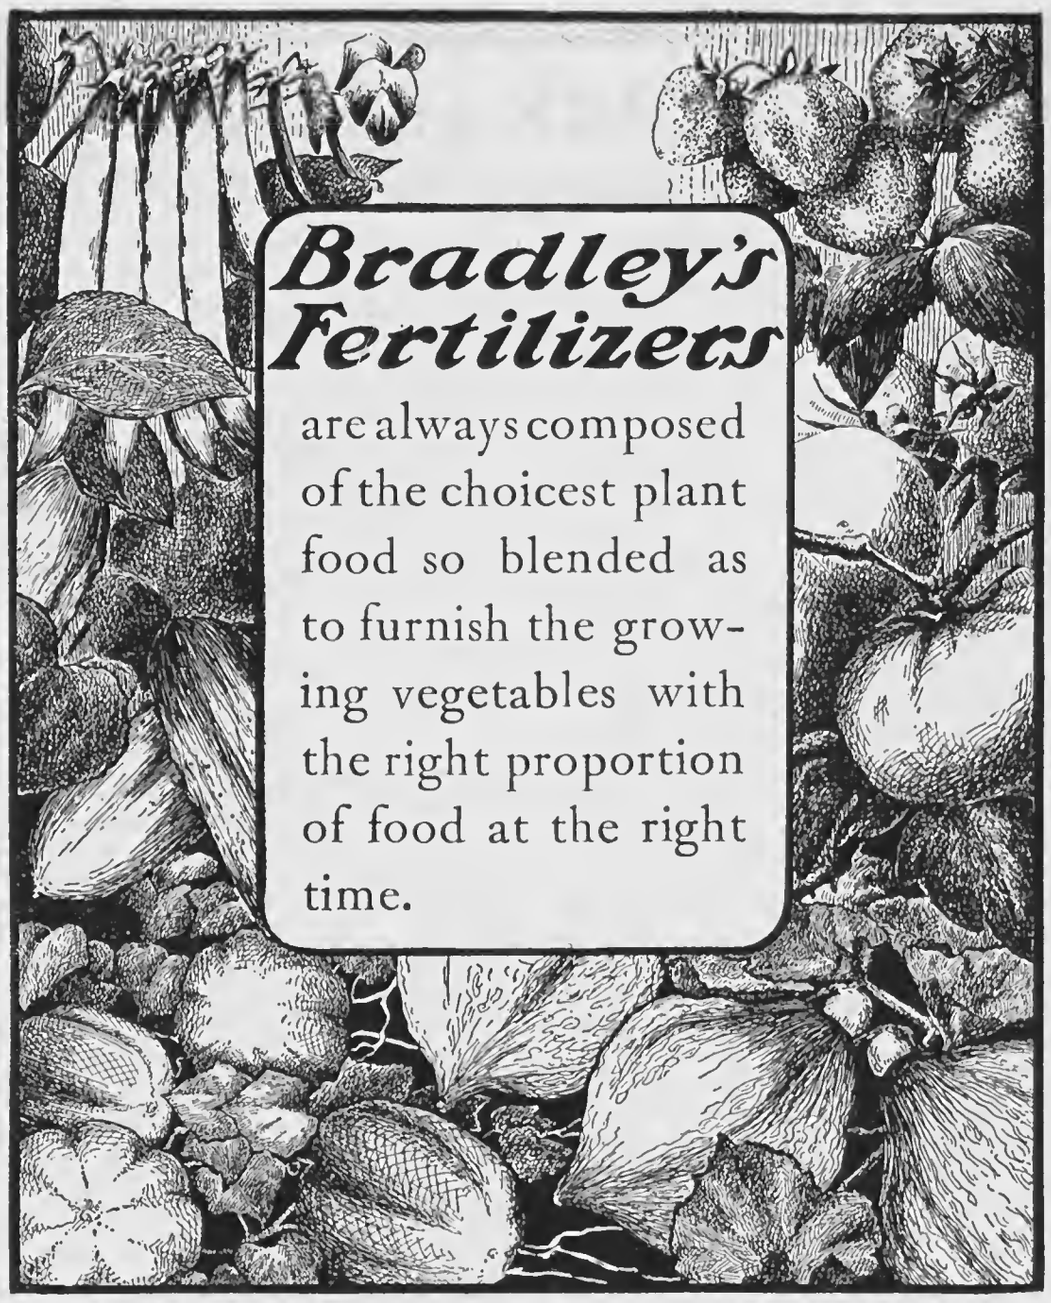
WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

Once or twice a year the good housewife has a thorough house cleaning. The house has been swept and dusted every day in the year, but the housewife knows that in spite of vigilance dust accumulates in cracks and corners, and is only to be removed by special effort.

It's the same way with the body. You look after it every day. You take all the ordinary precautions of cleanliness and health. Yet the body needs its special cleaning to rid it of the accumulations of waste and poisonous matter which invite disease. Doctor Pierce's Golden Medical Discovery, taken regularly once or twice a year, would save many a sickness. It purifies the blood, strengthens the stomach, and cleanses the body of poisonous accumulations.

"Last spring I had a severe attack of pneumonia, which left me with a bad cough, and also left my lungs in a very bad condition," writes John M. Russell, Esq., of Brent, Cherokee Nat., Ind. Ter. "I had no appetite and was so weak I could scarcely walk. My breast was all sore with running sores. I got two bottles Dr. Pierce's Golden Medical Discovery, which I believe saved my life. I cannot express my gratitude to you. I am able now to do very good work."

Dr. Pierce's Medical Adviser, in paper covers, sent *free* on receipt of 21 one-cent stamps to pay cost of mailing *only*. Address Dr. R. V. Pierce, Buffalo, N. Y.



The Most Successful
Tobacco Growers
accomplish results by forcing the early growth of their plants. This is successfully done by proper use of
Nitrate of Soda,
applied before the plants are six inches high. The immediate effect of an application of *Nitrate of Soda* is to develop a dark green color of the leaves and start the plants to growing rapidly. Just enough *nitrate* increases the yield and improves the quality. Write to **John A. Myers,** 12-O, John St., New York City, for full information. No charge.

THE BREEDER'S WAYSIDE.

Soiling Crops for Mules and Horses.

I work a number of cattle and mules, and wish to raise their feed. Almost anything grows here. What is best for soiling crops to get a balanced ration? What is the ratio of nutrients for work mules, also work cattle. Is silage good to feed to horses and mules and work cattle?

Birmingham, Ala. J. W. H.

Horses and mules cannot be fed green crops in so free a manner as cattle. They have smaller stomachs, and are liable to colic unless fed judiciously and in relatively small amounts. Consequently I do not regard the soiling of work horses or mules as desirable, excepting in a small way. Of course succulent food in a very limited way is desirable, and is appreciated by the horse. In the South Soy beans and cow peas fed with fodder corn will provide a splendid soiling ration where the balance is a good one. Both of these crops do well in the South, though the cow pea will produce the largest yield per acre by considerable. Then the Soy beans or cow peas will make a very nitrogenous hay of high class if well cured. The Alabama Experiment Station at Auburn should be able to offer valuable advice on growing these soiling crops, it being in the State from which the inquiry comes.

Horses at medium work require a nutritive ration of 1:6.2, while those in heavy work require 1:6. Mules have the same application so far as feeding standards go. Oxen at light work require 1:6.5, while those at heavy work require 1:5.3. A 1,000-pound horse at medium work requires two pounds, or if heavy 2½ pounds of digestible protein daily to 11½ or 14 pounds of digestible carbohydrates and fat. A 1,000-pound ox at medium work requires two pounds of digestible protein, or if at heavy work 2.8 pounds to 12 or 13.8 pounds digestible carbohydrates and fat. This for daily consumption. Silage is not especially adapted to horses. Horses will eat it, but it has been tried by some very extensive horse breeders and discarded as unsatisfactory. I know of no persons at this time feeding silage to horses. Its fermented character does not make it best suited to the horse's stomach. Sugar beets, however, are very good if fed in a small way. For cattle silage is especially suited, and a 1,000-pound steer will eat 30 pounds or so a day with a relish. Work animals, however, require concentrated foods for the best results, and this is not a quality of silage. So for either horses, mules or oxen I should recommend relying on standard hays and grains and feeding soiling crops or silage as an appetizer only in small amounts. C. S. PLUMB.

Pure Cornmeal vs. Corn-and-Cob Meal for Steers.

"Michigan Reader" wishes to know whether the policy of grinding corn for fattening steers is a good one. He says they pay one per cent for getting the cob taken out and the corn ground. Many experiments have been conducted where pure cornmeal and corn-and-cob meal have been fed cattle, and it has been clearly shown that 100 pounds of one gave about equal returns with the other. This is explained on the basis that where pure cornmeal is fed it packs rather solid in the stomach, while if the cob is in the meal, it makes a more porous mass, through which the digestive fluids pass more readily than in the pure meal. This applies in particular to cattle, whether for beef or milk. The Kansas Experiment Station has experimented on this subject more than any other station, so far as steers are concerned. They have fed pure cornmeal, corn-and-cob meal, and whole corn, dry and soaked. In 1884 five steers fed pure cornmeal 140 days ate 795 pounds of meal each for 100 pounds of increase, gaining 2.08 pounds per day, while five steers fed corn-and-cob meal ate 732 pounds for 100 pounds increase in live weight, making an average daily gain of 2.25 pounds. In 1885 the experiment was repeated, and continued for 150 days. In this trial 1,166 pounds of pure meal were required to make 100 pounds gain in live weight, or 1.36 pound gain daily was made on this feed. Of corn-and-cob meal, 1,260 pounds were required to make 100 pounds gain, or 1.44 pound daily gain per head. So both of these years the corn-and-cob meal gave the most satisfactory results.

It may not always pay to grind corn. If one has pigs pastured with steers, then such corn as may pass through them will be eaten by the pigs and a gain made thereby. But where the only purpose of the grain is for the steers then it should be ground or crushed. If not, there will be considerable loss from undigested grain passing off in the manure. At the Texas Station Curtis fed corn, cob and husk ground together, and coarse cornmeal to steers. It required 498 pounds of corn, cob and husk meal to make 100 pounds of gain, and the steers fed this made an average daily gain of 2.29 pounds. Those fed coarse cornmeal required 400 pounds of grain to make 100 pounds of gain, but they made a less daily gain, making 2.21 pounds. For years the writer has fed corn in various forms to live stock, and unless for some special experimental feeding, always gives the cattle, whether milch cows or steers, corn-and-cob meal. This we grind ourselves in a burrstone mill, but many farmers can, of course, grind their corn in sweep mills, which, however, are more or less unsatisfactory, or in regular farm mills as they choose. Yet I should certainly feed corn-and-cob meal rather than pure cornmeal. C. S. PLUMB.

Anybody

can keep his horses free from all forms of **Lameness**, curbs, splints, contracted cord, thrush, grease heel, etc., by treating promptly with

Tuttle's Elixir.

Used internally it cures Colic, Distemper, Founder, Pneumonia, etc. **Used and endorsed by Adams Express Co.**

Dr. S. A. Tuttle.—Dear Sir:—I have used your Elixir on one of the worst spavins that I ever saw on a horse, and it entirely cured the lameness. I also used it for rheumatism in my family, with just as good a result, and will cheerfully recommend it to anyone in want of a liniment. O. B. GOVE, Walts River, Vt.

TUTTLE'S FAMILY ELIXIR cures rheumatism, sprains, bruises, etc. Kills pain instantly. Our 100-page book, "Veterinary Experience," **FREE.**

Dr. S. A. TUTTLE, 30 Beverly St., Boston, Mass.

Beware of so-called Elixir—none genuine but Tuttle's. Avoid all blisters; they offer only temporary relief if any.

ZENOLEUM Kills Lice, Ticks, Mites, Fleas, Etc., on all kinds of animals and poultry. Given internally it drives out worms. Cures all cuts, wounds, sores, etc. Non-poisonous. Endorsed by leading veterinarians. "Veterinary Adviser" free. Zenner Disinfectant Co. 100 Bates St. Detroit, Mich.

TO GET MORE EGGS YOUR HENS MUST BE KEPT WARM and DRY USE NEPONSET RED ROPE ROOFING

To keep out wind, frost, rain and snow from Fowl-Houses there's no better low-cost roofing and siding than "**Neponset.**" Contains no tar. Given an occasional coat of paint it will last for years. Costs about a cent per square foot. Sold by dealers in rolls of 100, 250 and 500 square feet respectively, each roll containing necessary tin caps and nails. For a permanent roofing and siding use

Paroid Ready Roofing.

Postal brings Booklet, samples of "Neponset" and "Paroid," also name of nearest dealer.

F. W. Bird & Son, East Walpole, Mass.; Chicago, Ill.

VICTOR CORN & OAT FEED

Gives Results.

The American Cereal Co., Chicago, Ill.
Gentlemen:—I have fed Victor Corn and Oat Feed to my horses all the year. They have worked hard and they are looking fine. It is a good feed for horses. For cows, sheep and hogs we are using it with good results. I can fully recommend Victor Corn and Oat Feed.
C. W. SISSON, Almond, N. Y.

It is **results** you want—not theories. Remember this, that for
Feeding Beef Cattle,

Best Gall Cure on Earth
Mailed anywhere for 50 cents.
MOORE BROS., Veterinary Surgeons, Albany, N. Y

THE CHAIN-HANGING
Cattle Stanchion
The most practical and humane Fastener ever invented. Gives perfect freedom of the head. Illustrated Circular and Price free on application. Manufactured by O. H. ROBERTSON, Forestville, Conn.

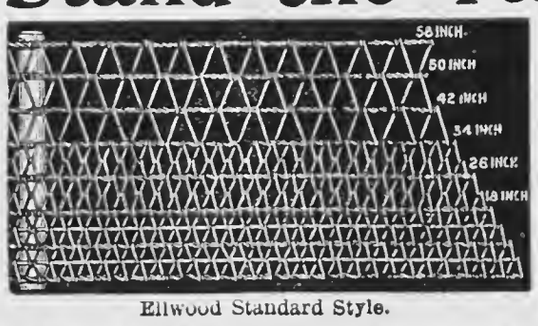
Wilder's Stanchion
—being an improvement over Smith's. Lightest, strongest, quickest, safest swing stanchion made. Has steel latch and automatic lock. Becomes stationary when open. Animal cannot turn it in backing out. Made of best seasoned hard wood. Pins for fastening with every stanchion. Send for testimonials.
J. K. WILDER & SONS, Box 30 Monroe, Mich.

Trade Mark.

LUMP JAW
Easily and thoroughly cured. New, common-sense method, not expensive. No cure, no pay. FREE. A practical, illustrated treatise on the absolute cure of Lump Jaw, free to readers of this paper.
Fleming Bros., chemists, Union Stock Yards, Chicago, Ill.

WELL DRILLING Machines
Over 70 sizes and styles, for drilling either deep or shallow wells in any kind of soil or rock. Mounted on wheels or on sills. With engines or horse powers. Strong, simple and durable. Any mechanic can operate them easily. Send for catalog.
WILLIAMS BROS., Ithaca, N. Y.

Stand the Test of Years.



Ellwood Standard Style.

ELLWOOD Steel Wire Fences
Best at the start, but making them better every year. Hard steel wire heavily galvanized. ELLWOOD FENCES do all that is required of them. Six styles, 18 to 58 inches. Every rod
FULLY GUARANTEED.
Agents sell them everywhere, but if you cannot find an agent write to the makers.
AMERICAN STEEL & WIRE CO., Chicago or New York.

Ailing Animals.

ANSWERS BY DR. F. L. KILBORNE.

Ringworm on Young Cattle

All my calves, for two years or more, have what is called here barn itch. When about three weeks old the hair comes off the eyelids first, then around ears, on head and nose, then gets scabby or warty. Once in a while one will have scabby spots all over. What shall I do for them? I fatten calves right along. The cows are not affected. E. D. W.

Huntington, Conn.

Paint the patches with the compound tincture of iodine. Care should be taken not to allow the tincture to get into the eyes. Repeat once a week, until they cease to spread, which will indicate that the parasite has been killed.

Shoulder Lameness in a Mare.

A six-year-old mare had shoulder strained last Summer by one side of hame breaking on hard pull, all the pull coming on the other side. She limps at times, and the injured shoulder is a little less fleshy than the other, indicating a light case of sweeny, I suppose. What treatment is advisable? F. B. T.

Visalia, Ky.

Apply a mild blister over the whole point of the shoulder, and also over the shrunken muscle along the shoulder blade. Repeat after three or four weeks if there is any improvement from the first. If there is no improvement take the horse to a competent veterinarian for examination.

Horse Passing Worms.

I have a six-year-old mare perfectly sound and healthy, but every few days she passes a worm from eight to 10 inches long, one-quarter inch in diameter. Will the parasites hurt her? H. G. D.

Loyalville, Pa.

The round worm you describe is the common Ascaris of the horse, and except when present in larger numbers, is comparatively harmless. Feed only a bran mash at night, and in the morning *before* feeding drench with two or three ounces oil of turpentine, well shaken up in one pint raw linseed oil. In an hour (and before feeding), give one ounce each best aloes and ginger, either in ball or by drench in a pint of cold water. Then follow with a bran-mash diet until the horse is freely purged. Salt placed where the horse can lick it at will, will materially diminish the number of intestinal worms.

Enlargement on Horse's Ankle.

I have a young horse (seven years old) which got his foot between two logs, one year ago in March, and dislocated his ankle. I put him in the barn, bandaged the injury, and, on examination, the veterinary said there was no fracture of any kind, replaced the bandage and said it would be all right in a few days. He ordered a liniment. The horse was not very lame, but I did not allow him to do any work for six weeks. There was a small enlargement on the inside of the ankle, which I have tried to remove with mild applications. Lately, from some cause, the enlargement has grown, and a small one commenced on the outside of his ankle. But for the blemish he would be worth $200. He is not lame. I used compound tincture of iodine and camphor. Once I applied a light blister of biniodide of mercury, just enough to raise the hair. It seemed to make it grow. What remedy do you advise? F. H.

Gallupville, N. Y.

If the enlargement is soft and puffy, blister quite severely with the biniodide of mercury ointment; but if it is hard and bony, I would advise having it fired in points. The firing should be done only by a competent practitioner.

Some Pig Questions.

Why do you prefer Berkshires, and is it healthful for the pigs to work in manure? How do you prevent them from scattering it all over the yard or field if you pasture them? C. R. W.

New Jersey.

We wanted a black pig. For several reasons the blacks seemed most desirable. As between Berkshires and Poland Chinas the former seemed better suited to our farm and crops. The Poland seems to be a corn-and-clover pig. On the rich corn lands of the Middle West the Poland is seen at its best. On our rough, hilly farm, where there is little clover, but a great variety of crops, the active Berkshire seems better adapted to the conditions. Our pigs have done well on the manure pile. They are in a large yard, and are not obliged to stay in the manure all the time. They work it over thoroughly, fine it and make it far better for spreading. They scatter the manure somewhat, but do no real damage to it. When the horses are fed whole corn the pigs require little extra feed in addition to it.

Dutch Belted Cattle Notes

The bull Belvidere was a superb animal, a remarkably sure breeder, and his calves averaged very large. One of them weighed 113 pounds when dropped. Last Fall, when three years old, he showed signs of crossness and, fearing he might attack my children, I sold him for beef. He dressed 800 pounds of beef besides hide and tallow. The tallow was inconsiderable, as he was not fat. I did not feed him as he should have been fed for fear that he would become vicious and unmanageable. He has a half uncle —Harry Byron—that weighs 2,060 pounds. A number of years ago I had a cow drop high-grade Dutch Belted twin bull calves. They are oxen now, and weigh 4,000 pounds. In January, 1900, I sold an old registered cow that weighed, empty, after having been driven six miles, 1,410 pounds. The butcher said that had she been weighed when younger and when at pasture she would have weighed 1,700 pounds. She gave me 196 quarts of milk in seven days, on silm pasture, two months after calving. She was an easy keeper and about an ideal dual-purpose cow.

New Jersey. G. G. GIBBS.

HARDY DUCKS.—As a breeder of ducks I wish to protest against the statements made in THE R. N.-Y. of March 30 about Pekin ducks. That Pekin ducks are not hardy is a notorious fact, and while they succeed well under the model conditions of the large duck ranches they often fail altogether for the farmer. There are several breeds which are hardier than the Pekin, the Muscovy, the Cayuga, the Grey Call and best of all that great little "egg machine," the Indian Runner. You can keep three on the food one Pekin eats. They are better foragers, make little noise, and lay more eggs than a Leghorn hen. They reach a weight of four pounds in the same time, and the meat is not so coarse and strong. R. D. B.

Cottons, N. Y.

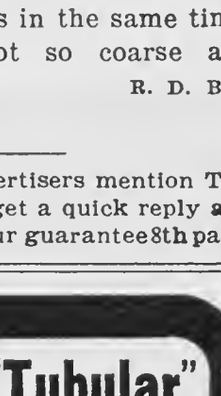
Sharples "Tubular" FARM Cream Separators.

If no agent will bring you a Sharples Separator, we will loan you one for trial free of cost. Though hundreds of our latest have gone on trial, not one has been returned. The truth is, they give more butter than any other separator, enough to pay big interest on the whole first cost, and they turn much easier (former capacity doubled with less driving power) and are entirely simple, safe and durable.

Separator improvements come fast here. These new machines are far ahead of anything else known. We have been making superior separators for 19 years (longest in America) and are proud of them, but these new "Tubulars" discount anything either ourselves or anyone has ever made.



Other agents will try and draw comparisons between their new machines and our old ones, but don't let them. Have a trial of a "Tubular" Dairy Separator, they are double the money's worth. Free book "Business Dairying" and catalogue No. 153.

Sharples Co., Chicago, Ills. P. M. Sharples, West Chester, Pa.

SEPARATOR FREE

on 10 Days' Trial. Lightest, easiest running HAND Separator.

NATIONAL Cream Separator

Free book tells all about it.

National Dairy Machine Co., Newark, N. J.

—DE LAVAL— CREAM SEPARATORS

The improved "Alpha" disc or divided milk-strata system is used in the De Laval separators only. Strong patents prevent its use in any other machines. The "disc" system makes the De Laval machines as superior to other separators as such other separators are to setting systems. It reduces necessary speed one-half, reduces size of revolving bowl, saves labor and power, enables simplicity and durability, skimming cold milk, running cream of any desired thickness, and insures absolute thoroughness of separation under all conditions, which is not possible with any other separator or creaming system.

Send for "20th Century" catalogue.

Quaker Dairy Feed

The Value of June Pasture

in producing the best milk is fully recognized by dairy experts. June pasture is taken as the standard of excellence in dairy feeds.

Quaker Dairy Feed is as perfectly balanced a ration as June pasture. It is a pure grain food scientifically balanced to produce the largest flow of milk and to properly maintain the animal. It is economical.

WELL SATISFIED.

WELLS, Vt., Jan. 9, 1900.

The American Cereal Co.,

Gentlemen:—I have used your feed for the last year and I am well satisfied that there is no other feed that will produce so much milk as Quaker Dairy Feed. Yours truly, A. MITCHELL.

Sold only in Sealed and Branded Sacks. Each Sack is stamped with analysis of contents, showing guaranteed per cent. of Protein.

If your dealer does not keep Quaker Dairy Feed, send his name to us and get a free copy of "Modern Dairy Feeding."

A FRUIT GROWER IN PORTO RICO.

WHAT THE COUNTRY LOOKS LIKE.

Chances in the Fruit Business.

TROPICAL FRUIT COMPETITION.—Fruit growers and consumers are interested not only in the fruits grown in the temperate zone, but also in those from the tropics, for with modern transportation the fruits and products of all climes, except those of a perishable nature, are brought to our markets and sold at our doors. Perhaps it will not be right to say that they are sold in competition with our northern fruits, for I do not know as a fact that the vast quantities of oranges, bananas and pineapples, consumed by the people of the United States actually compete in the markets with our apples, pears, peaches and grapes. I am inclined to believe that tropical fruits do not diminish the sale or limit the use of northern fruits; they simply round out the season, and give greater variety, so that the people consume a larger quantity. At any rate a kind Providence has provided a variety of luscious fruits, some that can be grown only in the tropics, and some only in the temperate zone, but all evidently intended for man's enjoyment and use, and all have become a necessity in modern times.

FROSTED FLORIDA.—Since 1890 I have had the pleasure of spending seven Winters in Florida and other southern States, I have gained some knowledge of the orange industry there, and, living on an orange grove on the banks of the Indian River during the disastrous freeze of 1894 and 1895, I have seen the results of the freezes since then. I remember looking at the ruined groves, considering Florida's uncertain climate, and saying to myself what a desirable thing it would be if Porto Rico or some other of the West Indian islands could become part of the United States, and make a fruit garden for us that would be truly tropical, where there would never be any danger of freezes. I never expected to see the day when this would be the case, but I have; our flag now floats over Porto Rico. Last Winter I visited the Island, spending nearly two months there, looking up its fruit growing possibilities, especially the orange industry, as well as I was able. I found the Island healthful, with fertile soil, a sufficient rainfall, except on the south side, and a tropical climate, a quartette of valuable characteristics.

WILD FRUIT.—As a commercial industry fruit growing was never developed under Spanish rule. Enough fruit was produced for home use, but little or none for export. Oranges and lemons grow wild, seldom receiving care or cultivation. All are seedlings; so far as I can learn there is not a grove or a single bearing tree even, of grafted or budded improved orange or lemon on the Island. The wild oranges may be divided into two classes, the Mirangha or sour rough orange and the China or sweet. The latter are juicy and sweet, and do very well for insular use, but are not very attractive. They have too many seeds, too much rag, and too poor keeping qualities to make them valuable for export. At present the business of up-to-date fruit growing is somewhat of the nature of an experiment. No one has yet demonstrated by actual trial just what a well-cared-for orange grove of improved varieties will do. There is no such grove on the Island, but it seems reasonable to conclude that if the wild fruit flourishes without care the improved will certainly thrive when properly cultivated. Nothing is being done by the native Porto Ricans to develop commercial fruit growing; they are watching to see what the Americans will do. If a few groves are started that prove to be successful and profitable they will naturally follow and imitate. At present very few know anything of the art of grafting or budding, or know that there is any outside market for choice fruit.

SCENE ON A FLORIDA PINEAPPLE FARM. FIG. 136.

STARTING ORCHARDS.—There are not many American fruit growers on the Island yet, but a few have been there two years. Their first attempts at orange growing were made by obtaining wild seedlings from the hills, planting them in rows, cultivating them and budding later. This plan has not been very satisfactory. Later quite a large number of trees of improved varieties were imported from Florida; many of these are growing nicely, but they seem to require some time to become acclimated. Some trees had apparently become somewhat stunted by being frozen back several times; some were ruined by heating while en route. After looking at the matter on all sides those best qualified to judge have decided that the best way to obtain Citrus trees for planting in Porto Rico is to sow the seed of the sour orange to grow stocks on which to bud improved varieties like the Washington Navel, Hart's Tardif, Sanford's Mediterranean, etc., and lemon seed for stocks to be budded with lemon, grape fruit, Tangerines, etc. Seedlings of the sour orange and lemon grown from seed planted a year ago on suitable soil, properly cultivated, are now fine, vigorous little trees large enough to bud. Of course this takes time, but it is the plan I adopted on my own farm purchased last year. It is located near Bayamon, nine miles from San Juan, the capital. The largest colony of American fruit growers on the Island has purchased in that locality. When I visited the Island again in January of the present year I decided to prepare 4½ acres properly by plowing, cross-plowing and harrowing. This was planted early in March, using 220 quarts sour orange and 17 quarts rough lemon seed. The drills are 3½ feet apart, seed one-half inch apart in drill. There has been plenty of rain, so that the seed can germinate readily. A quart of seed ought to produce more than 1,000 trees for grove planting. Other Americans have also planted considerable seed, so the prospect is that there will soon be a supply of home-grown trees.

SOIL AND WEATHER.—The per cent of land suitable for growing oranges and pineapples profitably is comparatively small, but at present such land is mostly unproductive, and can be bought near good roads within a reasonable distance of the seaports at a cost of from $5 to $20 per acre. The weather is remarkably uniform through the whole year. This can be accounted for by the fact that the great body of water surrounding the Island modifies the heat and cold, so that July is only a few degrees warmer than January. The United States Weather Bureau report for 1899 states that the highest temperature for that year at San Juan was 91 degrees in June, the lowest 65 degrees in November. People from the States will be likely to find the steady warm weather depressing if they reside there for a long time, but from my own experience I can say that a visit of a few months during the cold of our northern Winter is delightful. The rainfall at San Juan in 1899 was 81 inches, being the greatest in August, September, October and November, and least in February.

There are very few factories there to employ labor; nearly all the work is agricultural. There is a great surplus of farm laborers. The people are kind-hearted and willing to work. Employers are annoyed by many more applicants for work than they can use. The regular wages for able-bodied farm laborers are 35 and 40 cents per day, without board, boys 20 cents, oxen 50 cents per pair. Travelers who have visited the different West Indian Islands tell us the natural resources of Porto Rico are equal or superior to any of the other islands. It is the general opinion of those who know the Island best that fruit growing, especially oranges and pineapples, will soon become a leading industry. I think this the most promising business investment the Island offers. A word of caution may be needed here. It takes money to start a grove and care for it till it comes into bearing. The

purchase of the land is only the beginning: for the first few years it will be all outgo and no income. Still, there is this to consider: A thrifty young orange grove or promising pineapple plantation has a market value while still young, for there are many men of wealth who do not wish to wait, who will be glad to buy at a good figure groves just coming into fruitage. There is a sort of fascination about the beautiful orange tree with its golden fruit that captures the heart of the northern man. Again, what is true of the fruit grower in the North is just as true in the tropics, and everywhere else on earth. A successful fruit grower must be an enthusiast; must love his work, must love to see the trees grow; must have a large stock of perseverance, always remembering that valuable things cost. GEO. F. PLATT.

Connecticut.

PINEAPPLE CULTURE IN S. W. FLORIDA.

During the past few years pineapple growing has rapidly come to the front about St. Petersburg, Fla., which is situated on a narrow peninsula separating Tampa Bay from the Gulf of Mexico. It is across Tampa Bay, about 18 miles from Tampa. Owing to the closeness of the Gulf Stream on the west, Tampa Bay on the east, and the narrowness of the peninsula, which is only six or seven miles wide, vegetation rarely suffers from frost, thus greatly aiding the growers of semi-tropical fruits, of which the pineapple is one. The soil selected is usually oak and pine land, which must be thoroughly cleared and prepared as for the best garden work. This is sometimes quite a job, as the pine here has a way of sending a tap root down 10 to 12 or more feet, with just a fringe of small horizontal roots. The scrub palmetto, whose roots very much resemble those of the northern water lily, being from six to eight inches in diameter, also adds its share to the work. After being thoroughly cleaned up from two to four tons of tobacco stems, costing about $12 per ton, are plowed under. The sheds, which are one of the peculiarities of pineapple culture, are made by setting posts 15x7½, and 6½ feet above ground; on these posts 2x8 stringers are laid and upon these stringers 1x4 slats three inches apart are nailed. The whole pinery is then inclosed by a seven-foot tight board fence. The object of this shed is to protect the plants from cold winds and possible frosts. The pineapple also thrives better in the shade. This shedding is the most expensive part of the enterprise, costing from $500 to $700 per acre.

The plantation is then set out in beds of seven rows each, plants 18x30, with a five-foot alley-way. These alley-ways are left for the purpose of providing room to build small wood fires in case of very cold snaps. Not much dependance is placed upon the heat thus created, but upon the smoke, which retards radiation. This method of planting calls for about 8,500 plants per acre. The plants are of three kinds, viz., suckers from the side of the parent plant, rattoons, which are suckers with roots on, and crown plants which are from the tops of the fruit. These are planted very much as we plant cabbage plants in the North, except that they are much larger, being a foot or more long. We generally set from June to September, which is the rainy season here.

After culture is very simple, and consists in keeping the soil stirred with a scuffle hoe and fertilizing the plants about once in two months with some good nitrogenous fertilizer at the rate of about four ounces to the plant. Very little labor is required after planting, the plants soon shading the land, which with the semi-darkness of the shed is not conducive to weed growth. The crop is generally ready to harvest in from 12 to 18 months from setting. About 90 per cent of the plants commonly produce one fruit and three plants. After fruiting all except one sucker is removed from each plant, and used for planting new pineries. The sucker remaining is to produce the next crop and is cared for as before described. These suckers now sell for about 10 cents apiece. The cost of a pinery, including first cost of land up to fruiting, varies from $1,400 to $2,000 per acre; the proceeds are said commonly to reach as high as $3,000 for fruit alone, while the sale of plants sometimes adds about one-half more to the receipts. The varieties mostly used are the Smooth Cayenne and Porto Rico. My observation of the pineapple industry here is that it is of a very intensive character. The most profuse fertilization, intelligent care and faithful attention are necessary to success. These given the grower is abundantly remunerated. F. G. TICE.

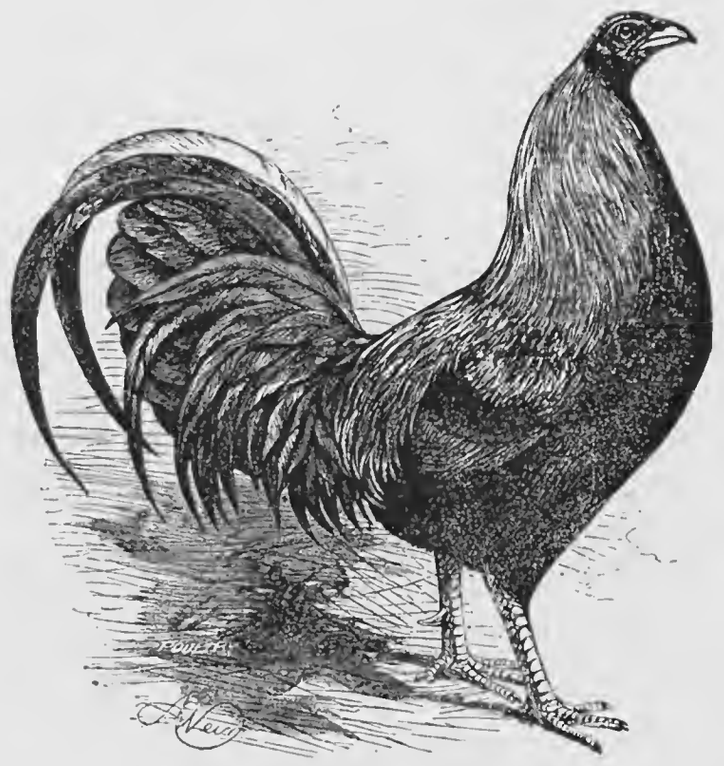
KILLING BEDBUGS.—Regarding the article on page 308 on bedbugs, I wish to call attention to the airing of the room after fumigation. It is absolutely essential to safety to provide means of opening windows *from the outside*, else sufficient gas is almost sure to be inhaled to insure work for the undertaker. Another point for safety; the cyanide should be dropped by means of a string from the outside. A third, but not so important, is to have the jar protected, not so much to prevent spattering as to prevent *leakage* through the vessel which often cracks from the heat suddenly evolved. Refer readers to bulletin from Entomological Division, Washington. I've followed their instructions with profit.

M. G. KAINS.

A USEFUL FOWL FOR THE FARM.

The genuine Game fowl is a comparatively rare bird in poultry exhibitions, and is quite distinct from the two types popular at present among fanciers. The modern or "exhibition" Game embodies the extreme attenuated idea as applied to fowls, and the close selection along these lines has done much to undermine the vigor and thrift of the variety. The Cornish Indian Game is another departure from the original type, this time in the direction of extreme blockiness of build and development of flesh. This kind also has departed from the normal state of hardiness, being among the poorest yielders of eggs. There would seem to be no economic advantage in having produced these two variations from the normal type. The true Game, or "pit" stock, as poultrymen designate it, needs no eulogist where once it is known and tested as a fowl for eggs and poultry. It is subject to much variety of size and shape, but the accepted type, where pains have been taken to control it, is a fowl of medium size, legs of moderate length, plumage quite full and tail especially of great length and beauty. The tendency of breeding exclusively for pit uses is to develop vigor to the highest limit, and there has been a movement among English fanciers in the direction of the normal type, such stock being now known as the Old English Game. Fig. 137 shows this type, being a reproduction of a pen-and-ink drawing by Weir, England's best-known artist in this field. It represents a bird whose bodily lines suggest a Leghorn, with the exception of head points.

There is much about the make-up of the genuine Game fowl which especially adapts it to the conditions found upon the average farm. Vigor is the true basis of prolific laying. In the Game is vigor conserved to the utmost. To allow stock of any breed to



A TYPICAL GAME COCK. FIG. 137.

fight constantly, whether in the instance of males or females, is to allow vigor to run to waste. There is no denying that it is the Game's first nature to fight, and the problem is to take up this breed of full pristine vigor, and so handle it as to direct its forces in the line of reproduction. It is not to be supposed that the cow which holds the butter record could accomplish this if kept constantly upon the warpath. The butter problem was worked out in the Channel Islands by a system of keeping the cows at the quietest pitch while under the pressure of high feeding. In the case of Game fowls there is abundant testimony that certain individuals and families are remarkably prolific layers, and there is every reason to believe that if fanciers would devote a tithe of the interest in supplying the pit Game with the proper environment to enable it best to develop prolificacy which they now squander in chasing some fad bubble or other around the lots, it would be much to the advantage of the art of husbandry. Let them take some of those improved nest boxes, so many of which have been patented in the past few years, allowing the egg record of each layer to be kept, and by the process of selection of the most prolific, prove to what extent the fighting nature may be restrained, harnessed up and turned into eggs.

There is another trait of the Game which, when the conditions are right, establishes its advantage over all other breeds. This is perhaps closely allied with its superior courage, which directs it to roam over wide areas in quest of forage. The Game will cover long distances, frequently a quarter of a mile, in search of grasshoppers and other insects. In my own experience I have found the high cost of food for poultry the chief objection to the pursuit. When tempted to push out into the rough lands, the hawks and crows have quickly responded, "Here is nature." I have often wished that my stock were of the right breed that I could say in turn, "Here is nature." So thoroughly ingrained is the Game's combative nature that the out-crosses upon other breeds will often display a surprising amount of it. I have known a Game Plymouth Rock hen leave the ground and fight a hawk upon the wing, in defense of her brood. The Game is your true Stringfellow breed, adapted largely to find its living while enriching our outlying orchards. The Game has not been popularly handled as a business fowl. Among the reasons for its neglect may be mentioned the high prices of stock. The breeders for the pit are generally limited to small flocks, producing no great amount of surplus, and the high prices obtainable for each lively male for use in the pit preclude selling at farmers' prices. So, while a Game cross upon common stocks would be advantageous, it is seldom available. The breed which most closely resembles the true Game, and one especially desirable from its make-up and useful qualities, is the Duckwing Leghorn, a variety not so many years over from England, where it originated. It is no secret that both the Game and Dorking, besides Leghorn blood, were used in its breeding. Specimens have been exhibited in our leading shows within the past half dozen years, which more nearly approached the accepted ideal for Leghorn shape than is found in our popular Brown or White varieties. They have never yet caught the belief that they are coming into popularity, which constitutes the chief ground for any breeds getting into favor with the masses. If true worth were the criterion there might be some startling occurrences in the poultry yard. F. W. PROCTOR.

A MADE-OVER DAIRY BARN.

A reader recently requested a plan for a cow barn to accommodate a stock of about 20 cows. For a person who has a location adapted, I think my plan could be but little improved. My old barn, about 80x36, stands about north and south on land gently sloping to the east, with cellar under it about eight feet deep. My stable was on the east side running nearly the entire length. By the new plan I took three spaces of 12 feet each, starting the sills at the old floor, and going out at right angles to the old barn 48 feet. The feeding floor is 12 feet wide in center, with cow stable on each side; the cows heads in, tied with patent stanchions. Running water in a tank at west end of cow barn supplies a tank between each two cows, connected by piping to first tank. There are 12-lighted 9x13 windows on the south side, which let the sun on to the cows all day, on the south side, and with windows smaller, about four feet long, about as thick as they can be placed in a monitor roof, furnish sunshine to the cattle on the north side of barn, and swinging in furnish ventilation when necessary. In the cellar, which receives the manure through trap doors, the ground is graded from both outsides to the center space sloping about four inches, and all the bottom is cemented. The center space under the feeding floor is graded toward the east end, slope about one foot. Every drop of liquid manure settles in the center; an eight-inch pipe through the east wall runs into a cement well outside the building, three or four feet deep, from which it is dipped with a long-handled pail, into barrels on a dray, and taken to any part of the farm where needed.

Under the old stable I had a cement basin, but when the droppings from above filled the space, the liquid was displaced and lost. Now my supply is always visible, and is wholly separate from the droppings, and the surprise is that so many barrels accumulate in a few weeks from 20 cows. Its use is a revolution in farming; it is, of course, full strength, and care is sometimes required in its use. Doors on each side can be thrown wide open, and carts placed close to the piles of droppings. A sliding door separates the cow barn from the other. The silo, 12x24, is nearly opposite and extends 12 feet west of old barn; the land being a little higher. A window about 10 feet from ground, serves to fill the silo about 24 feet deep.

Worcester Co., Mass. CHAS. E. PARKER.

Eggs and Meat.

T. Greiner, in the Practical Farmer, says: "I wish to take issue with the editor of THE R. N.-Y., who doubts the pertinency of the saying, "as full as an egg is of meat," because an egg is 75 per cent water. That is just about the percentage of the water found in meat. And when you see a little chick trying to get out of the shell, how much more meat could you expect to crowd inside of an egg shell?" The following table shows how eggs compare in food value with some other foods:

	Refuse.	Water.	Protein.	Fat.
Whole egg (hen)....	11.2	65.5	11.9	9.3
Steak	12.8	54	16.5	16.1
Cheese	....	34.2	25.9	33.7
Potatoes	20.	62.6	1.8	0.1
Milk	....	87	3.3	4.

The eggs of the duck and goose have a greater food value than those of the hen. A pound of steak has about 50 per cent greater feeding value than a pound of eggs, while a pound of cheese contains three times as much nutriment. An egg full of chick is far more "meaty" than the same shell packed with yolk and white. We know, of course, that eggs furnish strong and nutritious food. At this season of the year the workmen who do the heavy labor with metal, wood and stone, on the great city buildings, eat great numbers of eggs. They can be observed eating their dinners of fried egg sandwiches instead of meat.

FEEDING MUSCLE-MAKERS INTO PLANTS.

Its Practical Application in Feeding Grass Lands.

The recent publication of an article in THE R. N-Y. on the above general topic has led to a number of inquiries regarding its practical application in increasing the amount and value of the hay crop. The great lack in the leading forage crops of New England farms is protein. Such fodders as corn, oats and our common grasses are rich in starchy materials, known to chemists as carbohydrates, but are deficient in protein. The protein is especially useful in milk production, and in building up muscle in the growing animal, while the starchy part of the food is useful mainly for the production of heat. There are three methods by which the influence of this lack of protein in our crops may be partially counteracted; first by growth and feeding of more clover, peas, Alfalfa, vetch and Soy beans, all of which are relatively rich in protein; second by the purchase and use of such grain feeds as cotton seed, linseed and gluten; and third by increasing the proportion of protein in our common grasses, corn and oat fodders by the proper use of fertilizers. The first of these methods has been practiced to a limited extent, and should be more generally adopted. The second method is more common, but adds greatly to the cost of keeping the herd. The third method is practicable, but has received little consideration until within a few years. In the use of fertilizers the three important ingredients are nitrogen, phosphoric acid and potash. The last two are commonly known as the mineral ingredients of fertilizers. Whether we use stable manure, fish, blood, tankage, nitrate of soda, or sulphate of ammonia, they are all valuable for the nitrogen and the mineral ingredients they contain. It is a commonly-observed fact that the materials supplying considerable nitrogen, like stable manures, blood or nitrate of soda, greatly promote the yields and the growth of grasses, corn and oat fodder. But this is only one advantage from their use. The nitrogen of the fertilizer also tends to increase the nitrogen of the crop beyond what would be brought about by the increase in yield. That is, the *proportion* of nitrogen in the composition of the plant is increased.

The nitrogen in plants represents nearly a fixed part of an organic compound called protein. All protein compounds contain approximately 16 per cent of nitrogen, or 6¼ parts of the whole. If, by the use of liberal quantities of nitrogen in the fertilizer, we increase the nitrogen in the crop one-half of one per cent we increase the protein 6¼ times that amount, or 3.1 per cent. The effect of nitrogen on the yield and feeding value of hay is very well illustrated in an experiment by the Storrs (Conn.) Station, which covered a period of three years. In this experiment nitrate of soda and sulphate of ammonia were used as sources of nitrogen, but on different plots. The results from these two sources of nitrogen were quite similar, and the figures have been averaged in the following table, which gives absolute and relative yields per acre:

	Lbs. per acre.	Dry substance per acre.	Protein per acre.	Relative yields.	
No fertilizer	...	1,675	121	0.7	0.6
Dissolved bone black....	320	2,368	195	1.0	1.0
Muriate of potash.....	160	.....	...	...	...
Mineral fertilizer	480	3,240	248	1.4	1.3
Nitrate of soda, 160 lbs.	25	.....	...	...	...
Mineral fertilizer	480	4,202	366	1.8	1.9
Nitrate of soda, 320 lbs.	50	.....	...	...	...
Mineral fertilizer	480	4,458	432	1.9	2.2
Nitrate of soda, 480 lbs.	75	.....	...	...	...

The dry substance as here used means the total amount of food constituents exclusive of water, while the yields of protein were obtained by multiplying the dry substance by the per cent of protein in the crop from each plot. In the column headed "relative yields" it will be noticed that the yield of protein on plots that received over 25 pounds of nitrogen per acre increased relatively faster than the dry substance. This means that the percentage of nitrogen and of protein increased when more nitrogen was used in the fertilizer. The presence of some clover on all the plots obscured, somewhat, the effects of the nitrogen on the mixed grasses. In some other experiments on pure species of grasses the effects of nitrogen in increasing the protein were even greater than on the mixed grasses with some clover. The average percentage of protein for six distinct kinds of grasses, where only mineral fertilizers were used, was 7.4 per cent; where 25 pounds of nitrogen (equal to 160 pounds of nitrate of soda) were used with the mineral fertilizers, there was 8.6 per cent of protein; and where 75 pounds of nitrogen (equal to 480 pounds of nitrate of soda) were used, there was 11.6 per cent of protein.

The practical application of this is that the liberal use of nitrate of soda, or other quick-acting source of nitrogen, on meadows, will greatly increase the yield and the feeding value of hay. How much nitrogenous fertilizers we can afford to use depends on the value of hay and the price of nitrogen. It must be remembered that mineral fertilizers are essential in addition to nitrogen, unless the land is to be plowed and manured after fertilizing one year. Nitrate of soda alone will give a large increase in crop for one, and sometimes two years, but as soon as the supply of minerals is seriously reduced the yields fall off rapidly. Dissolved South Carolina or Florida rock phosphate, at the rate of 300 pounds per acre, with 150 pounds of muriate of potash, will supply a fair proportion of the mineral ingredients. Of late years nitrate of soda has been the most economical commercial source of nitrogen for grass. I believe that from 150 to 300 pounds per acre of this will pay on meadows where the manure supply of the farm is not sufficient for all crops. The liberal use of stable manure will have much the same effect as commercial nitrogen, however, and should be utilized to the fullest extent possible. Quick-acting materials, like nitrate of soda, or sulphate of ammonia should not be applied until the grass has become well started in growth in the Spring. If large applications are to be made, it would be advisable to apply at two dates, from three to four weeks apart. C. S. PHELPS.

EVERYBODY'S GARDEN.

With a little forethought and labor many dwellers on small city or village lots might enjoy the luxury of small fruits and crisp tender vegetables of their own growing, and at the same time beautify otherwise unsightly buildings and areas. The illustration, "A Barn Garden," Fig. 138, offers suggestions for this work. In this instance Lima beans, tall-growing tomatoes, cucumbers, nasturtiums and garden peas were planted on south side, just far enough out to escape drip from the eaves, and trained to the wall. Everything grew finely, and the yield was very satisfactory; from nine hills of Lima beans we used 28 quarts, worth four cents per quart, sold one-half bushel for 75 cents, and saved a quantity of seed. Two tomato vines yielded nearly a bushel of ripe fruits and a

A MICHIGAN BARN GARDEN. FIG. 138.

quantity of green ones for pickles. From two cucumber vines we had all we cared to use for slicing. The peas furnished but one mess for eating, and were then pulled up to give more room to the fine Caprice nasturtium, from whose vines we picked numberless bouquets, and whose leaves and blossoms furnished a dainty addition to many salads and garnishes. For Lima beans no better place than the south and east sides of such buildings can be found. Make the soil rich and mellow, and when the apple trees are in bloom plant the beans (eyes down) about one inch deep and 12 inches apart. Use coarse wool twine for the vines to climb, which they will do as readily as does a morning glory. Early Siebert and King of the Garden are our favorite varieties. Grapevines and even peach trees can be trained to such a wall, by proper pruning, and securing the branches by nailing strips of leather over them.

Eight or 10 roots of rhubarb, a Spring luxury, will furnish an ordinary family an abundant supply. Linnæus is best for early use, though not as large as Victoria or Mammoth. An asparagus bed 3x6 feet will yield several dollars' worth each season if properly cared for, and will last for 20 years. Anyone who has tested the difference between home-grown salads and those purchased from the grocery or market will gladly give time and space to grow a few rows of lettuce, endive, chicory, dandelion, mustard, parsley and cress. Several of these are useful as greens, and for garnishes. Raspberries, red and black; blackberries, currants and gooseberry bushes can be set close to the tight board fences which ordinarily enclose city lots, and if pruned and cared for, yield rich harvests, as well as hide the ugliness of the fence. Caring for the fruits and vegetables will keep the boys and girls off the street, and give them an interest in the home and a love for Mother Nature as nothing else can.

TIMELY SEEDS FOR MAY.—Below is given an alphabetical list of vegetable seeds which are timely in most localities for sowing or planting in May, viz., asparagus, beans, beets, cabbage, cauliflower, celery, corn, cress, carrot, cucumber, endive, lettuce, melon, onion, peas, parsley, parsnip, potatoes, radish, spinach, salsify, turnip and tomato. Many of these varieties may be sown or planted up to the middle or last of June. Some of the more tender sorts, as Lima beans, melon, cucumber and squash, may be advanced considerably ahead of their regular season by starting in shallow pans or boxes placed in sunny windows. Squash, melon and cucumber vines being very delicate and liable to injury are most safely handled in berry boxes. Enough seed should be sown in each box to make sure of a good stand after transplanting and becoming established in the ground. The boxes should be moved occasionally to prevent any roots that might grow out of the boxes getting started in the soil outside. When ready for transplanting, soak the boxes thoroughly, and with a sharp knife remove the bottom, and plant the entire box below the surface of the ground. Thus handled the plants will receive no check, and the time gained in maturing the crop will many times repay the extra labor. The very small, slow-germinating seeds, as celery, parsley, etc., are most safely handled in shallow boxes of any desired depth. Broadcast or sow in drills, cover lightly with fine soil, and cover the boxes with burlap or other coarse cloth until well established. Rich soil and plenty of moisture are indispensable, and boxes should be somewhat sheltered from too hot sun.

Lima beans can hardly be omitted either from the home or market garden; being particularly liable to injury from late frosts or even cold, wet weather, they should, for first early, be started as above. The bush varieties are growing very popular, both as to quality and yield, and will in a great measure supersede the pole varieties, especially where space is an object. Burpee's Willow Leaf, Wood's Prolific, Burpee's Quarter Century and Dreer's Wonder are all desirable varieties of bush Limas, and are named in order of their season. The pole or climbing varieties, the chief dependence of the market gardeners, are trained in various ways, on poles or trellises; the latest and best way is to set posts of 2x4 lumber 12 feet apart and eight feet high; 1x3-inch boards are nailed from post to post at top, and 1x2-inch strips at the bottom. Coarse wool or binder twine is cut in three-yard lengths and tied at both top and bottom boards, 12 or 16 inches apart. Not more than two vines should be allowed for each string, and the vines will need no assistance in climbing to the top; the leaders should then be cut or pinched out to throw the strength of the vine into the maturing of the pods. Rows four feet apart are sufficient for horse cultivation, and good crops are often grown three feet apart or less. Well-enriched ground with shallow but thorough tillage, is necessary to ensure good results.

Michigan. J. E. MORSE.

WHITEWASHING WITH SPRAY PUMPS.

I have recently seen a new factory building on the east side of New York City whitewashed from top to bottom, ceiling and walls, by a spray pump. The wash was made in the usual way, about as thick as cream, and strained through a fine sieve into an open barrel. The pump was single-acting, so constructed that it drew in a small amount of air with the wash at every stroke, and discharged it into a tank holding about 20 gallons. To this tank a long hose was connected and discharged through a one-half-inch pipe about 10 feet long. Two kinds of nozzles were used. One was an ordinary stop-cock, one-quarter-inch size, with one side sawed off near the plug and a slot cut down to it, so that when partly open the wash was thrown against one side of the slot, and discharged in a fan-shaped spray. The other was a brass plug screwed into the end of the one-half-inch pipe; two small holes were drilled through this plug at an angle, and over the top was screwed a cap with one hole in the center the size of one drilled in the plug under. Both of the nozzles threw the same shape of spray and one was as good as the other as far as I could see. A pressure of 60 to 80 pounds was used on the tank. A large colored man was the motive power, and the machine used a barrel of wash in from 30 to 40 minutes. The work was well done, and a large amount of surface quickly covered, but I think that the machine is too wasteful for painting, except the cheapest kind, as a lot of the spray does not hit where intended, and is lost. As I am much interested in spraying I noted the working of this machine, and have since tried both of these nozzles on fruit trees; they are of no use except for high pressure, say above 40 pounds, as it takes considerable force to make the stream spray and not dribble.

Rutherford, N. J. G. W. L.

THE rye stand throughout Columbia County, N. Y., is very fine, with every prospect of a large crop. New seeding is looking well. We are just having a copious rain, and all we want now is more warm weather. No wheat of any account is raised in this county.

Spencertown, N. Y. G. W. H.

Farmers' Club.

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see whether it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

Roofing Information Wanted.

J. T. R., Ivory, Md.—If any of your readers have used Ruberoid or Red Rope roofing for six years or more I would like to hear through THE R. N.-Y. what they say of it.

ANS.—We would like to hear from readers about this.

Paper Baskets for Fruit.

L. O. V. A., Bethel, Ky.—What do you think of paper berry baskets? Do you think they will answer the same purpose as the wooden ones? I think they will make a very neat package. They are cheaper than the wooden ones, if they will answer the same purpose.

ANS.—Dealers here do not think highly of paper fruit baskets. It is doubtful whether they will stand long shipments. When the fruit is moist the paper "goes down" rapidly. We would like to hear from shippers.

Fertilizers that Sour Soil.

W. O. B., Connecticut.—Does the use of acid phosphate increase the sourness of the soil or tend to sour it?

ANS.—Yes. It has been found that acid phosphate, muriate of potash and sulphate of ammonia increase the acid in the soil when used in large quantities. On soils naturally inclined to be sour it would be necessary to use lime every few years when these fertilizers were used. It seems to be true, however, that Potato-scab germs will not develop well in acid soils, and acid fertilizers may be better where scabby seed is used.

Fertilizer for Strawberries.

C. D. B., Wilmot, O.—Would it be all right to drill fertilizer with a grain drill on a strawberry bed before setting out plants? What kind of fertilizer do you advise?

ANS.—Yes, many farmers use the grain drill for dropping fertilizer. We would rather put the fertilizer in narrow strips (18 inches wide) where the plants are to be set. We think this is better than broadcast sowing. You can do this by tying the tubes on the drill together so as to drop the fertilizer in strips. The fruit and vine fertilizers made by the manufacturers are good. For a home mixture we like 400 pounds nitrate of soda, 400 pounds muriate of potash, 400 pounds fine ground bone and 800 pounds dissolved rock.

How Much Cement Needed?

J. C. L., Louisville, Ga.—I wish to build cow stalls and desire to make a cement gutter. Gutter will be 18 inches wide, six inches deep on one side and 10 inches on other, 60 feet long. Will require sides to gutter, so suppose it will be 36 inches outside to outside. How many barrels of cement would be needed? What fall would you give it? How much per foot, or how much fall in the 60 feet?

ANS.—In all the cities in this vicinity one orders cement, uses what he needs, and the seller takes back what is left. For this reason I have never estimated the amount of cement needed per cubic or square foot. Have so far estimated only the total cost—cement, gravel, sand, labor. Your job ought to cost from five to six cents per square foot—three inches of grout and full one-half-inch top coat. One of my men alone under my directions would do the work in one day, and it would take about two barrels of cement and four cubic yards of gravel. You could screen out of the gravel the sand needed for top coat. Two barrels best Portland cement $5, four yards gravel $2, and expert man for work $2.50. A cement contractor here would charge you for that job fully 14 cents per square foot, because it would be out of his line, and would make him trouble and care in forming the gutter. I would not try to curve that gutter, because it could not be properly plastered without a curved trowel. I would give it a fall of one-quarter inch to the foot if convenient. One-eighth or even less would carry off the fluid if not obstructed. I have a 10-inch drain 834 feet long with eight-inch fall, and the water runs quite rapidly. All the sidewalks in this city of 18,000 population *must* be made of cement, and there are perhaps a half dozen contractors for this work, and they make money at eight cents per square foot of walk. Beginners are apt to waste a good deal and spoil more, and therefore I caution such to go slow and take the utmost pains till they "get the hang of it." S. E. BARNEY.

Indiana.

What to Do With Bones.

Reader, Warwick, N. Y.—I have several tons of calf bones which have been in a pile until many are partly decayed. What method can I use to pulverize and put them in condition to use as a fertilizer?

ANS.—This question is asked every Spring. You cannot make fine bone meal on the farm without a steamer and powerful grinder. You can soften the bones by packing them in layers with wood-ashes. Put an eight-inch layer of broken bones at the bottom of a box or barrel. Then put a layer of unleached wood ashes, then more bones, and so on to the top. Keep the whole mass well wetted with liquid manure or urine. In 90 days the bones will be quite soft and can be smashed with a maul or heavy shovel. This will not equal the fine-ground bone which the manufacturers sell, but is about the best you can do on the farm.

Manurial Value of Corncobs.

G. S., Unadilla, Mich.—I wish to know the manurial value of corncobs. Can they be subjected to any treatment that will hasten decomposition and make them available for plant food? What soils will they benefit most? What fruits or vegetables will be aided by their use? Would there be value enough in their use to warrant the purchase of them? What could one afford to pay for them? The same questions apply to refuse cornstalks after they have been fed to stock. Would lime and plaster hasten the decomposition of either, and preserve the fertilizing properties?

ANS.—A ton of average corncobs will contain 10 pounds of nitrogen, 12 of potash and two of phosphoric acid. These fertilizing substances are worth only a few cents less than those in a ton of horse manure, yet it is clear that the corncobs plowed in as they are would not produce a good crop. It would not pay to try to rot them with lime. It is more economical to burn them. True, by burning you lose the nitrogen, but the fuel value will more than make up for it. A ton of the corncobs will produce about 17 pounds of ash, which is very rich in potash. There has been some argument about the difference in ash elements between corn kernels and corncobs. A ton of corn kernels when thoroughly burned would leave 30 pounds of ash—nearly twice as much as from the cobs. There would be eight pounds of potash and 13 pounds of phosphoric acid in the ton of kernels. We would use the refuse cornstalks for bedding and absorbents, and plow them under for manure. It is much better to shred or cut the stalks.

Plaster in the Stable.

F. B., Middletown, Del.—Ever since I can remember my father used to use land plaster on his barnyard manure when composting it, and I have followed his example. For some time past we have been following your advice by using it in our cow and horse stables, but we don't know just how much plaster we should use to hold all the ammonia and yet not waste the plaster. What is your advice?

ANS.—We consider it good practice to use the plaster in the stable. Formerly large quantities of plaster were used directly on the soil or in the manure pile. That practice has been largely given up. Prof. E. B. Voorhees, of the New Jersey Experiment Station, gives his practice as follows: "About one pound of plaster is used for three cows daily, though we are not particular in reference to this point, as we obtain the Rancocas waste plaster, which costs but $2 per ton, plus the freight. We sprinkle it in the gutters, on the platforms, and everywhere there is any moisture, and find that it absorbs very readily the odors, and probably fixes most of the ammonia, which would under other circumstances be lost." This "Rancocas" plaster is a waste product from the manufacture of phosphorus.

Prof. I. P. Roberts, of Cornell, gives his practice as follows: "We have used gypsum or land plaster in our stables for many years. About two tons suffice for the Winter for 20 cows. The stables are first cleaned and swept, for if a good deal of moisture is left in the gutters it will require rather more gypsum than we use. It is always sprinkled wherever the stable floors are damp from coming in contact with either solid or liquid droppings. There is no doubt in my mind but that this is not only scientific in principle, but thoroughly useful and beneficial in practice. In order to be available gypsum requires large quantities of moisture, and the liquids do not furnish more than is necessary to make available even the small quantity which I have recommended. I may say, however, that our stable floors are smooth, being paved, except where the cattle stand, with hard-burned bricks well laid. They were some that were not hard enough for paving in the city, and were procured at a reasonable price. Of all the flooring I have tried these bricks appear to be the best. They are clean and tidy, are easily swept and do not appear to dampen the stable like cement floors. I have no means of knowing, but I imagine the expense of such a floor is a little more than an asphalt or grout floor. However, this has worked so satisfactorily that I cannot but recommend this method of cow floor where one wants neatness, durability and comparative freedom from dampness. If wooden gutters more plaster than we use would probably be necessary.

MOTHERS.—Be sure to use "Mrs. Winslow's Soothing Syrup" for your children while Teething. It is the Best.—*Adv.*

The Cornell Reading Course.

Edited by John Craig, Professor of University Extension, and Editor Farmers' Reading Course, Cornell University, Ithaca, N. Y.

Reading Course Editor Among His Pupils.

The editor has just returned from a jaunt through Otsego, Herkimer, Oneida, Jefferson and St. Lawrence counties. It was a Reading-course excursion and very delightful. One meeting with a club or Grange took place each day, and sometimes two. This is a busy season, yet the average attendance was good. The editor saw a number of old friends, and made hosts of new ones. The social side of these meetings is quite as important as the intellectual. The Grange can be and is being made a great institution for good. Farmers need cementing agents which will tend to bind and hold them together—influences which will enable them to act in concert. The Grange dinner—here is a part of the all-day programme appreciated by all. The writer's knowledge of the products of cookery has expanded astonishingly during the week. His conception of the varieties of homemade pie, cake and pickled articles was much broadened, and his respect for certain kinds greatly increased. It was cheering to note everywhere a sincere and persistent desire to chase down underlying principles—to get at the why of things. This betokens the right spirit and promises well for the future. The season has been backward, but the land is drying rapidly, and seeding is being pushed with energy.

Time to Sow Hairy Vetch in the Orchard.

We would like to try some of the Hairy vetch. We could not very well plant it in August or early September, as at that time we are going over our ground picking fruit, but thought that possibly it could be planted in June or July, and would get large enough so that walking over it in fruit time would not kill it. We handle our Crimson clover in that way now and find it works very well. Is six cents per pound a fair price? M.

Lockport, N. Y.

I think it entirely practicable to sow Hairy vetch as early as July 1. If you keep your ground in a good state of tilth up to that time, the seed ought to germinate promptly, and you ought to get a good heavy mat of foliage on the ground before fruit harvesting arrives. The vetch will stand tramping better than Crimson clover, and makes an ideal carpet for fruit-picking. If I had to choose between September 1 and July 1 for sowing, I would certainly select the latter date. If you can secure the true Hairy vetch (Vicia villosa) for six cents a pound I think the offer is reasonable for this year. The seed seems to be scarce, and I have not been able to secure a better quotation. I have had better success in drilling the seed than in broadcasting, although if broadcast on freshly-harrowed ground and then rolled I have generally been able to secure a good catch.

Root-Gall of the Raspberry.

We have great difficulty in getting berry plants which are free from root-gall. Can you tell us whether there is any way of treating the plants before setting out, which will destroy the gall, so that we shall not be troubled with it on the stock grown from them? B. S.

Stanley, N. Y.

The life history of the root gall of the raspberry has not been satisfactorily worked out. Everyday experience has demonstrated the contagious character of the disease. I do not know any certain way of treating the plants so that the gall would be destroyed, and the roots of the plants left uninjured. I do know that there is, at the present time, a very serious difficulty in securing healthy plants. It is now coming to be generally understood that the gall of the raspberry and that of the peach are, if not identical, very closely related, and probably transmissible; therefore considerable time should be expended in examining the roots of raspberry plants which are to be set in young peach orchards. If I purchased a lot of berry plants which I suspected of root gall, I would certainly take the precaution of dipping them in formalin before setting out. I would use the formula employed in treating potatoes for scab—namely, one-half pint of formaldehyde diluted with 15 gallons of water. While there are no experiments on record which go to prove that this would lessen the amount and growth of the gall, yet I believe it to be worth trying. The principle effort to be made should be in the line of securing healthy plants.

Grape Knots.

A number of my Niagara vines are affected by swellings or knots like the samples I enclose. What is the cause, and is there any remedy? R. M. J.

Portland, N. Y.

The canes received bear irregular swellings, rough and warty, quite like black knot of the plum and cherry. These knots are not uncommon, and yet they are not so widespread as to have caused in any one place, a great deal of damage. The cause of these excrescences is not known at the present time. While they resemble in quite a remarkable manner the general appearance of the black-knot fungus, botanists claim that they are in no way related. French scientists have studied the matter carefully without reaching decisive conclusions. In this respect the trouble resembles Peach yellows, because its contagious character seems to be satisfactorily proved, but the fungus or germ has not been discovered. Some growers do not hesitate to say that the knots are due to unfavorable climatic conditions, but they also agree that when once they have started, they continue to grow and spread. Recent experiments published in an English journal claim that the trouble may be overcome by good tillage, close pruning and heavy fertilizing. This is a general principle in treating diseased plants. While it is true that Concords are much less susceptible to this malady than others, there is no guarantee that they will not finally become infested. I would cut out the diseased vines at once and seek to stimulate the vigor of those in immediate proximity, by good tillage, light dressings of nitrate of soda and wood ashes. If the vineyard has not had any barnyard manure for some time give it a dressing of the homemade article.

A Silo in Northern New York.

How can I build a silo in northern New York? Can I use green lumber? How shall I plant the corn, what distance apart and at what stage cut it? R. L. H.

Ellenburgh, N. Y.

A copy of the bulletin issued by the Cornell Experiment Station on the construction of the stave silo has been sent to your address. Green lumber can be used for staves, but we would prefer lumber which was at least partially seasoned. If you have made up your mind to build a silo next season it would be well for you to get out the lumber at once and have the planks cut two inches thick and one foot wide. The wide plank will season without warping out of shape, as will plank only six inches wide. Just before building the silo the plank should be taken to the mill and split in two, making the staves six inches wide by two inches thick. Corn should be planted for the silo but little thicker than it is ordinarily planted where a crop of grain is to be harvested. Best results seem to be secured when the rows are about 40 inches apart and the hills in the row from 20 to 22 inches apart, and not more than two stalks of corn left to the hill. The corn should be cut when the kernels are in what is known as the early glazing stage. The mistake is often made of cutting the corn when it is too green, and the mistake is also made of leaving corn until it is too ripe. Both should be avoided.

L. A. CLINTON.

Round Silos of Rough Staves.

Do you know of anyone who has built a round silo without having the staves matched or jointed, and who has used it for several years? Advice has been given to build with unmatched staves, and with matched. I would like to know which has proved the more satisfactory way of building. J. S. W.

Morris, Conn.

I have known of several round silos built where the staves were neither matched nor jointed, and where they were not even beveled. If the silo is to have a diameter of more than 12 feet it may very safely be constructed without beveling the staves or without tongueing and grooving them. If the diameter of the silo is to be less than 12 feet the staves should be either slightly beveled or else they should be of material not more than four inches in width. I have recently talked with several farmers, one of whom has had a stave silo in use for more than seven years. The staves of his silo are not beveled and he would not have them beveled, believing that they are better suited for the purpose as they are. L. A. CLINTON.

Tomatoes, Cucumbers and Cabbages

should be forced rapidly during their early periods of growth by a liberal use of

Nitrate of Soda.

When judiciously applied, these crops will be ready for market two weeks or more ahead of those not properly treated. The best results of *Nitrate of Soda* are obtained when used in combination with phosphates and potash salts.

For particulars and for ***list of dealers*** address **John A. Myers,** 12-O John St., New York City. No expense to you.

SPRAY PUMPS.

Ruralisms

NOTES FROM THE RURAL GROUNDS.

FISH-OIL SOAP.—Much is now being written about this odoriferous compound. While it has been known and used by professional gardeners for generations, it is only within the past few years tnat it has assumed first importance as a practical insecticide for the ordinary trucker and fruit grower. Under the name of whale-oil soap, various preparations of greater or less efficacy have long been offered by dealers at a comparatively high price. Possibly actual whale oil was used in making the early soaps, but those now offered are composed of ordinary fish oil, pressed from the mossbunkers and menhaden, so plentifully taken along our coasts, combined with an alkali. When soda is used the result is a tough, leathery soap often difficult to dissolve and keep in solution. It handles well, however, and is the kind mostly kept in stock by dealers in horticultural supplies. When potash is employed as a base a jelly-like "soft soap" is formed, retaining about 25 per cent of water in combination. The potash fish-oil soap is quickly and completely soluble in hot water, and does not separate on standing, though solutions weaker than one or two pounds to the gallon may decompose in warm weather if kept too long. We have tried both kinds, and find the potash soap far more effective and pleasanter to use. It appears to be more searching in its effects on vegetable and animal life than the soda preparation, and the proportions recommended for nse on greenhouse and tender plants—two ounces or more to the gallon of water—are quite too strong for best results. We find one-half ounce to the gallon sufficient for green fly or aphis, one ounce for Mealy bugs and soft-bodied insects, and two ounces for most glasshouse scales, dissolving the given qnantities in all cases in a gallon of water. Used in these strengths very little damage to tender young plants is caused. When scales or stubborn pests affect palms and other hard-leaved plants solutions as strong as eight ounces to the gallon may safely be used. For use outside the soap strengths should be at least doubled for the same class of pests. We strike a tough customer, however, in the Pernicious or San José scale. He is sealed so tightly in his scaly shelter when dormant that a two-pound-to-the-gallon solution is needed to overcome him. A solution of this strength is quite thick when cold, and must be used warm or it will not go through a spray nozzle. It may be safely applied to all dormant deciduous trees or shrubs, and is fairly effective, but experience shows that it seldom kills all the scales, even when very thoroughly applied, but greatly retards their spread. Crude petroleum must take precedence of all soap solutions as regards efficiency in killing resistant scales and other insects, but it often injuriously affects young trees, and sometimes kills them outright. Its use is necessarily limited to dormant trees in Winter and early Spring: as Summer applications pure or in the form of emulsions have often injured the foliage considerably. Fish-oil soap, up to four ounces to the gallon, may be sprayed all over the trees whenever the larvæ of the scale is observed during the growing season, but all stronger solutions should first be tried on a single limb of the trees needing treatment. Any injury to the foliage will be apparent in a few days, and the solution weakened accordingly by the addition of more water. The claim is made that potash fish-oil soap, as now made, is a good fertilizer for many plants on account of the contained potash, which, we have been informed, amounts to a very substantial percentage of the product, and the presence of some nitrogen due to organic impurities in the cheap grades of oil used for the purpose. This is quite conceivable, and our own experiments show that weak solutions applied to the soil about tender plants rather stimulate than retard their growth. The most important use for fish-oil soap, apart from its employment in fighting Pernicious scale, is as an effective application for the very destructive new Pea louse. Hundreds of barrels of this soap were used last year in New Jersey alone, generally with profitable results. The best potash fish-oil soap we have yet tried is made by James Good, Philadelphia, Pa. The price for the pure soap ranges from four to five cents a pound, according to quantity purchased. A combination is also made with tobacco extract, which is especially useful for aphides, but the cost is somewhat greater. The compound Sprayall soap, made by Leggett & Bro., New York, is also very efficient and safe to use. It appears to have antiseptic as well as insecticidal properties and its aromatic odor renders it less disagreeable to handle than some others. A foreign soap preparation called Black Insecticide soap is strongly recommended by the highest European authorities and is now offered in our markets. We have not yet tried it.

THE BARBERTON DAISY.—A new plant of great interest and prospective decorative value has been recently brought from the Transvaal. It is a somewhat tender perennial, requiring good Winter protection, and produces great numbers of very large daisy-like flowers, on long stems. The color is almost pure bright red, a very rare shade in the family of Compositæ, to which it belongs. The botanical name is Gerbera Jamesoni, but Barberton daisy has been proposed for popular use, as it is found near that South African town. Some plants growing in the Riverton, N. J., nursery of Henry A. Dreer were very handsome last Fall, and it has since been successfully bloomed under glass in Winter. It is a handsome and striking flower, and the cultivation appears not difficult.

THE AGGRESSIVE STAR OF BETHLEHEM.—The hardy little Star of Bethlehem, Ornithogalum umbellatum, has become firmly naturalized in moist and shady places near the Rural Grounds, and even creeps into the fields and ousts the early grasses. One woodland glade is so entirely carpeted with its vigorous foliage at this season that it appears a perfect sea of green, in pleasant contrast to the fields, which are still quite brown at this writing. So thickly have the bulbs developed in the course of years that thousands are forced to the surface every Spring for lack of room. The pretty white star-shaped flowers follow in May after the foliage, now so vigorous and erect, has begun to decay. Where the clumps have grown so thick as to starve the bulbs there is not much bloom, but younger colonies flower with great freedom. The hardy Star of Bethlehem is a native of Europe, and was early introduced in American gardens It can frequently be found about old places, but is seldom planted now, as it is too aggressive for the flower border when conditions suit it. It is occasionally offered in bulb catalogues, and care should be taken to distinguish it from the large Winter-blooming species, O Arabicum, which is a pleasing plant for window decoration, and is often forced by florists for cut flowers. W. V. F.

THE BOIKEN APPLE.—Having recently heard several inquiries about the Boiken apple, I am moved to tell through your columns what little I know of it. Three years ago, upon the advice of S. D. Willard, of Geneva, N. Y., I grafted a large number of trees, 20 years old, to the Sutton Beauty and Boiken. Last Fall they bore some fruit for the first time. On one tree of Boiken there were more than two bushels of fruit; every apple perfect, although the tree was not sprayed. They are large, beautiful as wax. Color light yellow, with a crimson cheek. They are a little tart for dessert purposes, but for cooking, I believe that they are unexcelled. Although they are of good quality, yet I am confident that their handsome appearance will always find for them a ready sale. J. C. J.

there can be no scorching. The Automatic Agitator and a brush keeps strainer free. Brass valves; indestructible. Book on Spraying with terms to agents Free.

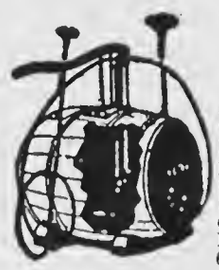
FIELD FORCE PUMP CO.,

2 Market St., Lockport, N. Y.

THE LIGHTNING COMPRESSED AIR SPRAYER. Patented 1900.

Holds four gallons. Pump in a little air with the pump which is attached to the reservoir. No more labor required. Will kill all kinds of insects. Will spray two rows of potatoes at one time and as fast as the operator can walk. Big money for Agents.

D. B. SMITH & CO., Utica, N. Y., U. S. A.

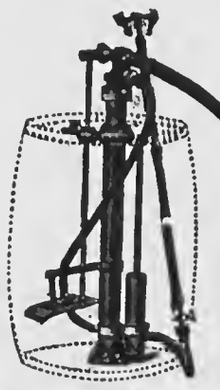


THE "HARDIE" Spray Pumps

are the most powerful, easiest worked, most modern, simplest in construction and moderate in price. DON'T BUY A PUMP until you have sent for our catalogue "C" and treatise on diseases of fruits, etc., sent FREE.

Hardie Spray Pump Mfg. Co., 66 Larned St. W., Detroit, Mich.

Buy a Good Spray Pump



—don't experiment—costs money. We have done the experimenting—used the common spray pumps in our own orchards, noted their defects—then invented the ECLIPSE. You get the benefit of our experience free. Send at once for catalogue.

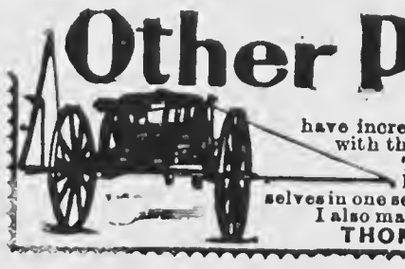
MORRILL & MORLEY, Benton Harbor, Mich.

$5.00 Compressed Air Sprayer for $3.75

It is admitted by all classes of fruit growers and farmers that my 5 gallon compressed air sprayer is the most durable made. This reduction is made for a limited time only. Take advantage of the liberal offer—it may be your last opportunity to get the sprayer at the reduced price. $3 75 for galvanized steel, $5.00 for copper. **Will throw a good stream 25 to 30 feet.** Good pressure 20 to 30 minutes. **The tallest fruit tree can be sprayed.** Order to-day. Salary to reliable men. Address

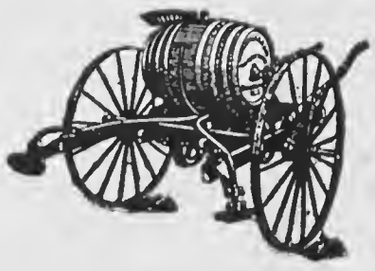
MARTIN WAHL Rochester N. Y.

Other People's Profits



have increased 25 to 50 per cent. when they began to spray *the right way*—with the right sprayer, the PEPPLER AND CLIMAX SIX-ROW SPRAYERS. They will do as much for you. Read how they spray 30 acres a day, how they save ½ the poison, increase crops one-half, pay for themselves in one season. Catalogue contains spray calendar, formulas, etc. Sent free. I also manufacture the Improved Riggs Plow and Riggs Furrowers.

THOMAS PEPPLER, Box 60, HIGHTSTOWN, N.J.



A Perfect Sprayer.

The "SCHANCK" 8-row will spray any kind of liquid poison.

IT has no small nozzles to stop up.
will not spray on horse or driver.
has no pumps, pipes, blowers nor cog-wheels.
will do more work better and with less trouble than any other sprayer. Price, $55. Send for circular.

JOHN R. SHANCLE, Mfr., Hightstown, N. J.

Hope Farm Notes

THE SUN SHINES.—After making a gloomy record of only two sunshiny days in the month, on April 26 the sun actually climbed over the hill and drove the clouds out of sight. Those who claim that "like cures like" had an argument right then, for the blue sky quickly helped the "blues" that had been gnawing at us for weeks. It was wonderful how the grass and growing things jumped at the sun. The first fruit trees at Hope Farm to show green were the crab apples, which leaved out April 23. Some early varieties of pears came next. Before the sun came one could see from our hill clumps of red where the maples had started, and light green where the willows woke up early. After 24 full hours of sun every living thing on Hope Farm began to dance. Even old Major realized that Spring had come, and let go of his Winter's coat of hair, so that he plastered those who rode behind him. The grass, rye and clover took on the dark, rich green which means serious business. I undertook to tell how the sun encouraged the work and production of chlorophyll. Some of the Hope Farmers got it that I said *glory feel.* That was not so bad, considering how every living plant daneed in the sunshine. Take it all through, April will go on record as a strange month. Some young men, and older ones, too, know how a sweetheart or a wife may drive them almen, and older ones, too, know how a tears by turns, and just when he is ready to run away turn with a sudden smile and make it all up.

FARM NOTES.—The sun brought work as well as whitewash for the blues. We were at least two weeks behind with all plowing. Our soil is naturally moist and heavy, and days of hot sun are required to dry it. The rain had given a chance to shred all the corn fodder, cut the Summer's wood and get ready for the start. The horses, too, were ready after their good rest. . . . . My friend De Voe, the weather prophet, assured me that I could not plant potatoes until May. He came close to it, but we did manage, by hard hustling, to get a few in on April 30. We are planting in hills this year—mostly early varieties. . . . . As an experiment we are planting Junior Pride potatoes grown on our farm by the side of Maine-grown seed of the same variety, and also second-crop Florida seed. We also have our regular-crop June Eating seed, and the second crop from Florida seed. This sort of testing is an old story, but I want to try it for myself. . . . . Prof. H. H. Hume, of the Florida Experiment Station, sent us a number of cabbage plants for trial. I have often wondered whether the southern plant, grown out doors from the seed, would be better than our northern hotbed plants. This Florida cabbage was started January 10 in the open air, and the plants were transplanted once at least. They are fine stocky plants—some of them having stems as large as the thumb. They stood the long journey well, though some of the outer leaves were yellow. We have them all out and we shall have a good chance to compare them with the "leggy" plants grown in the hotbed. At present I will back Florida against hotbed. . . . . If I were to put in a new set of water fixtures I would never again run a pipe direct from the pump to the house. The pipe that supplies our house leaves the main pipe a few feet from the pump. When the windmill is running there is a thump and jar, for then the pressure is brought against the range and our kitchen water works. I would rather have two pipes—one feeding from the tank to the house. This would cost more, and we would have to use tank water entirely; still, I think it would be more satisfactory.

ALL SORTS.—Various "cures" for a kicking cow are coming in, but I will guarantee that Julia will kick the cure out of them as fast as presented. She is in a class of her own—without rivals. The two calves bunt and punch her from every point of the compass. No matter how hard they punch and pull she stands meekly by and seems to enjoy it. The moment a milker's hand touches her ever so gently she is up in arms—or rather legs—and the whole thing is changed. If some active and wealthy man wants to try some new cure for kicking he will find Julia a ripe specimen. I have known wives to say that their husbands were too tame—did not "kick" enough. I will positively guarantee that Julia's society will remedy this defect, and I will sell her at beef figures. . . . . Our potatoes follow last year's corn. We were noticing how clean the cornfield is this year, and how much easier it will work than last year's sod. That is where we get the benefit of that last thorough hoeing we gave the corn. I doubt if we got our money back in the corn crop, but it destroyed the weeds, kept the ground clean and this year's potato crop will be better for it. On a farm we cannot live or work for to-day. Sometimes our best work must wait for years before we can read the results on Nature's face!

H. W. C.

HOPE FARM REVISITED.

A year's work, worry and expense does not always make as much visible improvement on an abandoned farm as might be imagined, but a recent brief stroll over the loafer fields of Hope Farm revealed a wonderful sticking up in the general appearance of the land. Cow peas and a good chemical fertilizer did the work on the back fields, and manure, fertilizer and good tillage on the nearby ones. Much hard work has of course been done in grubbing brush and getting bowlders out of the way. The unwelcome discovery was made that some of the big "hardheads" are cemented in rocky union to very ribs of the earth. In other words, there is an occasional outcrop of bed rock on the slopes. The soil is, however, of an excellent natural quality and quickly responds to good treatment. Cultivation of the steep slopes and thin spots will be given up as soon as a good covering of grass can be secured. H. W. C. is rather pessimistic as to the outcome of the Clark grass-seeding experiment; more so perhaps than the present appearance of the field indicates. This plot was prepared with the most scrupulous care, and an excellent germination of the seed followed, making a good close stand, but the Winter rains have since gashed and furrowed the sloping portions in a depressing manner. The prospect remains, however, of a sod so thick and tough that further pranks of the kind will be prevented. This promises to be a very useful experiment even if it only demonstrates the limitations of the Clark method. A good soil, excessive care in forming the seed bed and heavy seeding are essential factors, but in addition thorough protection against floods and untimely droughts is also needed to insure reasonable success. This is characteristic of all attempts at intensive cultivation. The planter may do his full duty in any case, but in the long run he will find that only narrow areas of fortunately situated soil will fully reward him for his trouble and expense. Despite the keen investigation of many agricultural problems now going on in our well-equipped experiment stations, very few facts of practical value to the ordinary cultivator are discovered, which seems to prove that agriculture is really one of the most difficult of all sciences. When humanity emerges from the present fog of military and commercial barbarism it will take its proper place as the most attractive as well as useful of all pursuits.

A Stringfellow peach orchard was being planted with a careful attention to detail that should delight Mr. Stringfellow's heart. It did look as though the chances for these little stubs of top and root-pruned trees to live were slim, but a few weeks' time will tell the story. The weather has been distinctly favorable for this experiment, as it has since rained heavily enough to settle the soil well about the little trees. The Hope Farm man should certainly be commended for the thorough manner he is carrying out the many experiments deemed of possible value in the rehabilitation of this long-neglected farm. It means no small expense and labor thoroughly to carry out experimental work of any kind. It is safe to say that any feature that passes the Hope Farm scrutiny will be of real value to the everyday farmer. If succeeding years bring as radical improvement in the appearance and capabilities of Hope Farm as the past one it will soon be a model well worth studying.

W. V. F.

SCRAPS.

THE homemade telephone has largely gone out of use. The cheap attachments sold by dealers are so much better and less liable to get out of order that it does not pay to bother with homemade devices.

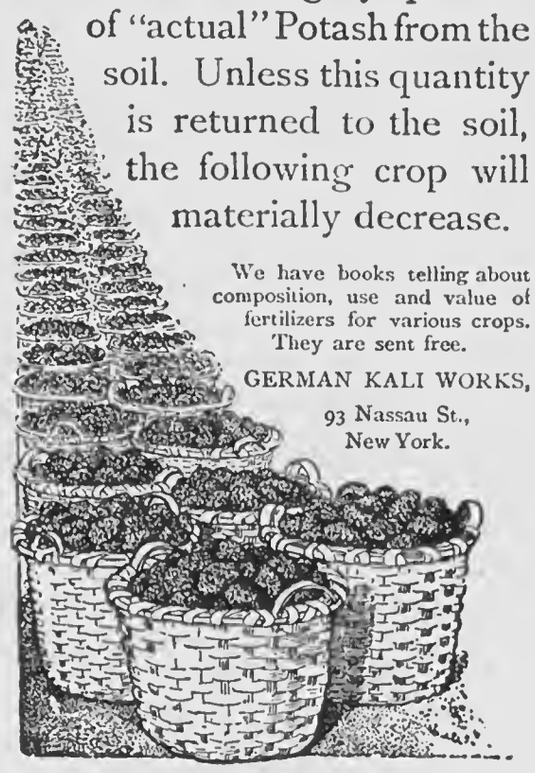
THE fertilizing value of corncobs may best be obtained by burning them. The little nitrogen they contain will be lost in this way, but there is not enough of it to pay for the expense of reducing them with chemicals.

GENERALLY speaking it will pay to drill in and cultivate cow peas rather than sow them broadcast. The growth of vines will be enough greater to pay for the extra trouble. It is not wise to expect much from this plant in the way of fodder and hay so far north as Canada. The better way is to plow them under and depend for profit upon their fertilizing value.

CORN SMUT AND STOCK.—A Wisconsin reader who fed cornstalks through the Winter had a sick horse, and the veterinarian said that Corn smut might have caused the trouble. Prof. W. A. Henry wrote him as follows: "Experiments in feeding Corn smut to cattle have shown that it is not generally at least an active poison, even if fed in very large quantities. There have been no experiments with horses. The quantity which your horse could possibly have got is so small that I feel quite sure that sickness must have come from some other cause than smut in the fodder. Corn forage is a splendid horse feed, being quite free from dust and exceedingly palatable, as well as more economical as compared with hay. I strongly urge that you continue the use of corn forage, therefore, looking to some other cause for the sickness of your horse."

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

Two hundred bushels of potatoes remove eighty pounds of "actual" Potash from the soil. Unless this quantity is returned to the soil, the following crop will materially decrease.



We have books telling about composition, use and value of fertilizers for various crops. They are sent free.

SATURDAY, MAY 11, 1901.

WE find that many people are interested in Porto Rico. We do not think that there is likely to be any large emigration to the Island, still there is a class of people who would without doubt do well there. For this and other reasons we have arranged for some reliable articles describing the actual chances to be found in Porto Rico. Jack Frost seems to have put his heel on northern Florida, but he will long and beg in vain for a chance at Uncle Sam's new island.

*

THERE are always those who say that apple growing will be greatly overdone The facts and figures of February generally silence such men, for in most years there is a lack of fine apples in late Winter. They may be right in saying that people are *planting* too many apples. Planting used to be 75 per cent of the business; now it is but 25 per cent. Spraying, cultivation and storage are now nearly as important as planting. The Jericho road that runs between the apple orchard and the fine market is a rough highway. The barrel of apples will strike 10 thieves where it formerly met one. Happily science has given us many new Samaritans also.

*

THREE years ago a laundryman in Rochester, N. Y., left his horse and wagon standing on the street. A steam automobile came along. The horse took fright, ran, and injured the wagon and himself. The owner recovered damages, but the county court reversed the judgment, holding that automobiles have a right on the road or street, and that horses must get used to them. The appellate court has now upset this decision and decided against the automobile. It appears to hold that the automobile is a small steam engine subject to the laws of the road which govern such machinery. This seems to us fair. The horse has enjoyed the rights of the road for centuries, and he should come ahead of the horseless carriage.

*

THE new buildings at Ellis Island, New York, for the reception of immigrants, are the most complete in arrangement and equipment of any that have been made for this purpose. Features of special note are bathrooms and laundry. In the laundry nearly 20,000 garments per day can be disinfected and thoroughly washed, and the bathrooms will accommodate 1,000 bathers per day. All immigrants who for any reason are obliged to remain on the Island over night will be made to take a bath. It is thought that such an initiation may have a salutary effect on these prospective citizens, and prove something of an incentive toward keeping clean afterward. What they will think when, later, they get into some of the political "deals" of this country, where no laundry is provided, is quite another thing.

*

THERE are many credulous people who believe themselves heirs of unclaimed estates, either here or in Europe, and they are willing to put time and money at the disposal of rogues who fatten upon such claims. Recently a woman was arrested at Richmond, Ind., by Federal authorities, on the charge of using the mails to defraud; she was secretary of an association formed to recover a great estate in Maryland, which is believed to be a myth. The alleged heirs, scattered over many States, have been furnishing money to prosecute their shadowy claims. One would hardly believe such frauds possible when the suppositious estate is located within the United States, but they prosper amazingly as do all of the get-rich-quick schemes. Foreign consuls often send warnings from abroad regarding imaginary fortunes lying unclaimed in the Bank of England, or unknown estates in some far-off corner of Europe. Rainbow chasing is never very profitable, and it will be well to put the energy thus expended into digging out prosperity at home.

*

THE transportation committee of the Eastern New York Horticultural Society met with representative farmers and others May 3 at Newburg, N. Y., and laid their grievances before the express and steamboat men. There has been much dissatisfaction among shippers at the careless way in which fruit is handled and the shiftless manner of returning empty crates. The committee made a strong showing, and there were men enough present to show that they mean business.

*

No, my scientific friend, the fact that you publish a good bulletin dealing with some fact or method does not settle the matter for good. Many people will not take the trouble to read it. Many will never know it was published. Some will read and forget it—others will not understand it. The only thing to do is to keep at the public. You cannot lift a sack of fertilizer or a bag of grain by getting above them and reaching down. You get down to their level or a little below them and lift up. In like manner, if you wish to get the farmer to know what the fertilizer or the grain is composed of, you must get down to his level and lift him into it. You may say that it is not your business to do this work of education. You discover facts rather than make them popular. We are not prepared to deny that statement, but if you issue bulletins at all, why not aim closer at the people who most need your facts?

*

AN interesting statement has been made regarding the national debts of the world's great nations. In 1793 it was estimated that the total debt of the nations was $2,500,000,000. It is now estimated at $31,000,000,000. The increase in debt, population and coin during the past century may be stated about as follows:

Increase in population	150 per cent
Increase in gold and silver	300 " "
Increase in debt	1,000 " "

It will thus be seen that this vast world's debt has largely exceeded the increase in coin, and must be based largely on credit. What has caused this frightful increase of debt? Possibly one-third resulted from building railroads and improving rivers and harbors. The rest may be charged to wars—many of them unholy and little short of barbarous! This is the burden that agriculture has carried—for, in the end, the great expense of war and destruction must come out of the soil.

*

WE begin this week a series of articles on dairy farm topics by H. E. Cook, of New York. Mr. Cook is a successful dairyman. He can milk a cow with his own hands, make the milk into butter or cheese, and sell the product to advantage. He can then take the pen and tell just how it was done, so that all may follow him. We regard Mr. Cook as one of the best dairy writers in the country. Our readers are sure to be helped by his articles. In a private note Mr. Cook writes:

> In 1899 we had a dry season, and potatoes were a good crop. Last year another dry season, and the conditions of the two crops were reversed, so after all it is a question of doing one's best and never losing faith in the Great Ruler. Did you ever think that the farmer of all men lives on faith, and I'm not sure but he may live as well as other people!

Of course he may if he will live up to his faith. No matter how the rain now falls, dry days are ahead of us, and we shall hear much of soiling crops this year. We try to promise by performance, and will let Mr. Cook's articles speak for themselves.

*

THE recent failure of a banking house in Seneca Co., N. Y., has proved a severe calamity to that part of the State. Among the reasons given for this failure is the following:

> The failure was a direct result of the decline in farm values. Many of the mortgages held by the bank were taken when farms hereabouts were in demand at $75 an acre. The same farms can be purchased to-day for $40 an acre. As an inevitable result the bank was more than $50,000 short in its April collections and failure followed.

We have no doubt that this statement of cause is correct. When these mortgages were given, the higher values were justified by the earning capacity of the farms. Through no fault of owner or tenant farm values have been forced down by reduced prices and increased competition. This shows what we have always maintained—that there can be no permanent prosperity in this country unless the farmers are generally prosperous. A shrinkage of farm values through reduced prices or inability to sell farm products is sure sooner or later to affect injuriously all forms of business and property. Money invested in land ought to be the safest possible investment, for the soil is the great mother of all industrial life. The farm that has shrunk 40 per cent in earning value cannot pay off the debt contracted at the higher figure without pinching the pocketbook of the men who lent the money, or the life of the farmer who struggles to pay it. Since the Civil War the National policy of this country has been to build up the town and city at the expense of the farm. Such prosperity will surely prove to be hollow unless the farm be given a fairer chance and the special favors granted to other classes be taken from them.

*

STRANGE and brutal things are done in the name of "sport," and about the most inexcusable and disgusting that we know of is the practice of pigeon shooting as carried on by some gun clubs. These pigeons, practically tame birds, are let loose, and frequently considerable scaring is necessary on the part of the attendants to make them fly, so that the brave Nimrod who is to murder them can get a shot. It often happens also that instead of being killed outright they are only maimed, and have to suffer for some time before being put out of their misery. It would be a nearly parallel case if a farmer should get his hired man to chase his flock of White Leghorns or Plymouth Rocks until some of the frightened birds flew over the fence or on top of the henhouse, while he blazed away at them, and then went about the neighborhood bragging about the glorious sport they had had. Of course, it is great markmanship for a man to hit with a rifle 95 out of 100 birds set loose for his benefit, as one did recently, but it is an act of cowardice second only to Herod's slaughter of the innocents. His skill could be shown nearly as well by shooting at glass balls or some similar moving target. Why sacrifice for mere fun the lives of helpless, harmless creatures? A man with such a fever for hunting should go into the jungle after lions, tigers or poisonous snakes, where he takes an even chance with his victim.

*

BREVITIES.

"THE WOMEN'S HORSE."

[In view of the recent discussion in THE R. N.-Y. regarding a horse for the women folks to drive, we have been asked to repeat the following]:

Ain't got no speed; he's fat enough to kill—
  Jest sorter jogs along a steady course,
An' yet there ain't no hundred dollar bill
  That ever'll buy old Gray—the women's horse.
I don't expect he really earns his feed,
  Jest cultivates a little an' that's all;
Yet he's exactly what the women need,
  To hitch up now an' then an' make a call.
You know how women drive—jerk on the bits;
  Push on the lines, an' cluck an' holler "whoa"!
Enough to drive a nervous horse to fits,
  But some old pelter like old Gray will go
Like clockwork—why, he'll turn right out an' pass
  Another wagon—patient as a saint,
Ef they broke down—he'd go to eatin' grass,
  An' when they whip him, he makes no complaint.
I feel as safe as can be when old Gray
  Takes out them women folks—he's old, I know,
An' now an' then I hear the women say
  They wished they had a horse that ain't so slow,
An' yet I'll bet they'll miss him when, some day,
  He strikes the last hard milestone of his course.
No! No! There ain't no money buys old Gray.
  I couldn't sell him—he's the women's horse.

WHO can wear light heels with a heavy heart?

BETTER "give your self away" than sell yourself!

THE widow may contribute her might through a broom.

PLANNING for the child is like building castles in the heir.

WHO can tell us about the paper fruit baskets? Are they useful?

THE cynics say that every man has his price. What is your price to-day?

TAKING a post-graduate course—the horse that breaks his bridle and runs.

"LET us put away childish things." Some men need help to get rid of them!

WHY is a sitting hen like a strike leader? One sits on the eggs and the other eggs on the cit.

THE hatchet is the only thing that will cure some hatches that never should have been hatched.

NO—the farmer's wife is not a hired girl taking a post-graduate course and tied up so that she can't run away.

THE hired man who takes a real interest in his work! You can't keep him down. If his present boss will not raise him some one else will.

IT is surprising how many people use an extra b in spelling plum. The time to use the b is when you are trying to get the rows straight.

THE latest so-called "consumption cure" is based on the observation that persons with gout or rheumatic troubles seldom have tuberculosis. The uric acid in the blood is thought to antagonize the tuberculosis germ. Those who have suffered from gout or gravel will hardly want to try this cure!

A PLANTER in Arkansas is said to be contemplating the establishment of a kangaroo ranch. Besides the value of its hide, the kangaroo supplies the tendons used by surgeons to sew up wounds. Probably the Arkansas man realizes that the profits from such a venture must increase by leaps and bounds.

Events of the Week

DOMESTIC.—Measles in a cavalry regiment stationed at Fort Leavenworth, Kas., practically disabled the entire command. . . . . A track is to be built along the Miami and Erie canal in Ohio, and the boats will be towed by electric motors. Experiments with the system have demonstrated its feasibility. . . . . A bill has been introduced in the Illinois Legislature making it a misdemeanor to give future options in markets, to spread false reports concerning stock values or to corner a market. . . . . Rosebud mine, at Angora, Mo., caved in April 26, and buried five men at a depth of 110 feet. . . . . During the last week in April heavy rain and snow caused disastrous floods in the Eastern, Middle and Central States. Conditions were very serious throughout the Ohio Valley, and in the vicinity of Pittsburg, Pa., where the loss was estimated at $2,000,000. At Cincinnati the river was 10 feet above danger line April 26, after which it fell slowly. . . . . The Southern Peanut Company, chartered at Norfolk, Va., April 27, with a capital stock of $100,000, has to some extent cornered the market for No. 1 Spanish peanuts, of which they have bought a large quantity of late. They will operate 40,000 nickel-in-the-slot machines, now building, which will dispense the nuts roasted, boiled in cocoanut oil and salted. A solid train of 50 cars of nuts left Norfolk April 27 for Chicago. . . . . April 30, a gusher of oil was struck in the Aspen tunnel of the Union Pacific, near Evanstown, Wyo. Much excitement prevails. Pennsylvania, California and Nebraska capitalists have secured large tracts of land, and will bore for oil. Local parties have also ordered machinery and will sink oil wells. . . . . A fire in a coke plant at Latrobe, Pa., April 27, killed six persons, and caused a property loss of $150,000. . . . . Cherry County, in the extreme northwestern part of Nebraska, was being devastated by immense prairie fires April 26, the recent drought and high wind lending to their fury. The region is sparsely settled, but several ranches have been swept away by the flames. Stockmen and villagers have turned out in large numbers to engage in back-firing, but the scope of the flames is so great that human agency avails little. Large herds of cattle have stampeded and are hopelessly scattered. Several villages are doomed unless rain comes speedily. The prairie grass is heavy and dry in all parts of the county. The flames traveled northward under three separate heads.

ADMINISTRATION.—Minister Loomis, returned from Venezuela, says he does not expect severing of diplomatic relations between United States and that country, and that war talk is foolish. . . . . Free trade between Porto Rico and the United States will be established after July 1, the local assembly having passed a tax law to meet necessities of the government. . . . . The Congressional appropriation of $3,000,000 for the extension of the rural delivery postal service becomes available in three months, and Chief Machen of the Post Office Department is now getting ready to spend it. The rural delivery routes cost an average of $500 a year each, and, allowing $500,000 for clerical hire and other expenses, it will be possible to establish about 5,000 new routes.

PHILIPPINES.—The court martial of Capt. James C. Reed, charged with frauds in the commissary department, began April 29. Numerous witnesses testified to payments made the accused officer, some being in the form of lump sums, others commissions on sales. Lieut. Townley of the navy is also implicated, and his conduct will be investigated by a naval board.

GENERAL FOREIGN NEWS.—Great loss of life and destruction of property was caused April 26 by a terrific explosion in a chemical factory at Griesheim, in the Province of Hesse, Germany. . . . . Bubonic plague continues to spread at Cape Town, South Africa, a number of fatal cases occurring among Europeans. The disease still causes alarm in Australia.

FARM AND GARDEN.—The Minnesota Legislature has passed a number of bills affecting farmers. A new law prohibits the sale of oleo or any imitation butter colored yellow, and makes such sale a misdemeanor. Formerly the stuff was allowed to be sold if properly labeled. The Torrens system of land-title registration is to be tried in the counties of Ramsey, Hennepin and St. Louis (the counties embracing St. Paul, Minneapolis and Duluth). If it proves a success in these counties it is to be hoped that at the next session it may be made applicable to the whole State. The gross-earnings tax bill, which was passed after a hard fight, provides that with the sanction of the people at the next general election, the railroads of the State shall be compelled, after January 1, 1903, to pay a gross earnings tax of four per cent in lieu of all other taxes.

The Harrison bill introduced in the Pennsylvania Legislature to prevent the use of any coloring matter in pure butter, which was intended to aid the oleo interests, has been killed. The Lack bill requiring all packages of renovated butter to be distinctly labeled, passed finally in the House.

The business to come before the next convention of the National Live Stock Association to be held in Chicago during the first week in December, will be of unusual importance, according to a bulletin issued April 17 by Secretary C. F. Martin. He says the live stock men and others interested will be compelled to continue their fight against the Grout bill, as the dairy interests have declared their intention to reintroduce the bill in the Congress. In addition to this the Association is interested in securing Federal inspection for all inter-state shipments of live stock in place of repeated State inspection.

The meeting of the American Guernsey Cattle Club in New York, May 15, will be a very interesting one, the result of the second home butter contest being announced.

A violent duststorm occurred in North Dakota April 27, and much of the wheat seeding must be done over again, as the grain was blown out of the ground. The temperature reached 84 degrees.

Ex-Gov. Morrill, of Kansas, has set out an apple orchard of 64,000 trees, on 880 acres of land, in the southern part of Leavenworth County. This is the largest apple orchard in the United States, if not in the world. The trees are set on the Welihouse plan.

April 30, the Snyder Anti-oleo bill was passed by the Pennsylvania House of Representatives. The debate of two hours' duration before its passage was one of the liveliest of the present Legislature. The bogus butter advocates threw off all disguise and acknowledged the sale of colored oleo on an enormous scale, in defiance of the present law. Dairy and Food Commissioner Jesse K. Cope and some of his agents, who have claimed that the law is being enforced, were embarrassed listeners to this frank confession. The Agricultural Department had been forced into passive submission to the will of farmers on the Snyder bill, which at first was bitterly opposed by Secretary Hamilton and his subordinates.

Plans have been agreed upon for a new Department of Agriculture building at Washington, to cost not exceeding $2,000,000. It will be U-shaped, of white marble, four stories high, with a 400-foot front and two wings, each 200 feet long.

May 3, representatives of the Eastern New York Horticultural Society, the Apple Shippers' Association and the Granges of New York State met at Newburg, N. Y., to discuss express rates and transportation matters as applied to fruits. Their efforts are calculated to obtain better recognition for fruit growers from transportation interests.

NEW YORK MILK PRODUCERS TALK.

About Cows and Their Feed.

The cows in this vicinity came through the Winter in good shape. The farmers buy their cows mostly, and they are worth from $30 to $60, according to time of dropping calf. But very few farmers raise their calves; the breed most liked is Holstein. There are no cows for sale except those brought in by dealers. J. L. R.

Westtown, N. Y.

Owing to the shortage of fodder in 1900 and the consequent scarcity, cows have been poorly wintered, and many dairies are now in bad condition for the Summer. I know of but few cows that have changed hands this Spring. Those fresh in milk sold for $35. Cows are mostly native, with a sprinkling of Jersey, Guernsey, Holstein and Durham. Most farmers raise their own heifers. Some are looking for sires that will increase size of cattle, as there seems to be most money in having prime veal calves. G. E. MCM.

Brecsport, N. Y.

The condition of cows varies according as the owners are feeders of grain or not. Probably more than half the cows are in prime condition, while the rest range from poor to fair. Very few farmers are buying cows; nearly every dairyman raises his own heifers. There are more Holsteins raised than all other breeds combined. Fresh cows are being shipped from this locality during all seasons of the year, and are being replaced by heifers raised on the farm. Fresh cows sell all the way from $40 to $65, according to quality and age, black-and-white taking preference over any other color. H. P. C.

Unadilla Forks, N. Y.

Cows in this vicinity in good condition, the silo supplementing the shortage of hay. Quite a few farmers are buying cows, as there is a good demand for milk. There are two milk stations at this place, H. S. Tutthill, of New York City, having opened his station April 1. He buys by test, paying full Exchange price for all milk testing 4.7 per cent butter fat, milk testing above or below paid for according, at the rate of two cents per .1 per cent. Cow buyers have been around paying from $30 to $40 per cow. The better strains of Holstein-Freisian cows producing large quantities of medium-quality milk are most satisfactory, even when milk is sold by Babcock test, as a good large flow of four-per-cent milk will net better returns than the smaller quantities testing higher.

Cobleskill, N. Y. W. J. W.

Many cows were sold during early Fall and Winter, owing to a very short hay and corn crop. The dry weather shortened the corn production so that many silos were only half or two-thirds filled. Prairie, or what is known as western hay, sold readily here for $15 per ton. As far as I have seen or heard cows are usually in fair condition. Most of the farmers raise their own heifers from their choicest cows. The Jersey cow and her grades have taken the lead as butter cows, but the past few years have made quite a change in favor of the Holstein. We have some very good herds of both breeds, notably the latter. There are not many cows offered for sale at present in view of the fact that the farmer thinks he can reach grass without much additional expense. Some cows are changing hands, however, at prices ranging from $25 to $35. The farmers here have come to the conclusion that the butter and cheese factory, side by side with the milk shipping station, develops a healthier market for whole milk, and that if substantial benefits are secured for the producer it must come along these lines, assisted by pure-milk laws and the passage by Congress of the Grout bill, or some equally as good legislation. M. D. W.

Spencer, N. Y.

Owing to the severe drought last season the hay crop was the shortest that has been in years, many farmers not having half hay enough to carry their stock through the Winter, and consequently, cows have been fed very sparingly of rough fodder. The past six months have been a harvest for the feed dealers. Sugar-beet pulp has been fed to some extent with satisfactory results, having been shipped from Binghamton and Lyons sugar factories. Notwithstanding the short hay ration cows have come through the Winter in good condition, and also in good health. All surplus stock was disposed of last Fall, and but few cows are being bought by farmers this Spring at from $30 to $35 per head. The majority of farmers raise their own heifers, as they make better cows than those they buy. Holstein-Friesians are preferred; a good many farmers are using purebred bulls and grading up their herds, while others already have herds of purebred and high-grade cows. New York buyers, when through this section, will pay more for black-and-white cows than for any others. But few cows are for sale here this Spring. The Empire State Dairy Company is paying 74 cents per can for milk at their shipping station here. E. C. J.

Greene, N. Y.

This is not very much of a dairy section; nearly all small dairies, with the exception of a few who ship milk direct to Jersey City. These dairymen generally buy cows to replenish their dairy, but most of the dairies are kept in stock by raising their own heifers, which consist mostly of Jerseys and Holsteins. Cows fresh with calf brings from $40 to $50, but not very plentiful to find. Cows have wintered fairly well, taking into consideration the scant supply of fodder sown last season. Barns will be about empty by the time cattle go on pasture. Milk is too low in price, when we take in account the cost of production. Those that ship get about $1 per can; those who patronize the shipping station get 80 cents per can, one-half cent less than Exchange price.

Stanton, N. J. W. A.

The cows in this section came out in fair condition this Spring. Some dairies are very thin. Those that make Winter milk are in good condition. There have been many auctions in this section during the Winter and Spring. Many farmers are out of hay, and at the present price of hay and grain they say they cannot afford to buy for their stock; hay is selling from $15 to $18 per ton in the barn, and hard to get at that. At the auctions the average price is about $40 per cow; if Holsteins it is nothing uncommon to sell for $50 to $60. Everything that is black and white is called a Holstein, whether it has a drop of Holstein blood or not. That makes from $10 to $20 difference in the price. The Standard Dairy Company is paying 74 cents per can for milk at Mayburys; at Solon the Dairy Dispatch is taking the milk since April 1; price supposed to be the same as at Mayburys. B.

McGraw, N. Y.

Last Fall everyone seemed fully to understand that he must reduce his stock, and this was done by selling off the older cows and young animals. With two very dry seasons the farmers made preparations early by putting in, up to June 5 or 6, a large acreage of fodder corn. Those not having silos cured and fed dry by cutting up a quantity at a time upon the floor in heaps, which heated and softened so that the stock ate it well and kept in fine condition with a grain ration, the same as with silage. Stock is looking as well as in former years. A number of farmers have had to buy some hay, but there were others who had a surplus and have supplied all demands at from $13 to $14 at the barn. One farmer now has about 50 tons to press. About the usual number of cows have changed hands, largely at auction, selling all the way from $35 to $50 per head. For a few years past considerable attention has been given to raising stock, mostly Holsteins, though there are several Jersey stock farms. W. F. J.

Earlville, N. Y.

Vegetables in the South.

The cabbage crop in this section is moving freely; 40 cars left here last night for the East and West. I find the farmers are distributing their stuff more to the West than in past years. They have been very much disappointed in the cabbage crop this Spring. Sixty per cent of the crop was planted in the extra early type of Wakefield, and set out early. For the past two seasons this type of cabbage has made heads of fair size, yielding about 150 crates per acre, came in early and brought big money. This year at least 60 per cent of the crop in this vicinity was planted in this early variety of Wakefield cabbage, and the season has not suited them. It has been an unusually cold Spring, and this type of cabbage has headed up very small, 100 to 250 heads to the crate, enough heads in one crate to make five under ordinary circumstances. Those having Henderson's Large Type Wakefield, Henderson's Early Spring, and Henderson's Succession cabbage are making fine crops. On account of the shortage in the yield of Extra Early Wakefield crop there will be no more cabbage shipped from this and Charleston's vicinity than there was the last year. This will make the crop of Spring cabbage very short. In the cold snap of the early part of the week the thermometer went down as low as 36 degrees, but a stiff wind blew all night and prevented much damage from frost. The potato crop of this section was nearly ready to bloom. It was not injured, beans were not hurt to any extent, but the cucumber and cantaloupe crop was scorched up badly by the cold wind and light frost. I think we are exceedingly fortunate in saving our potato crop, which is very fine. With favorable seasons from now on the new potatoes will be moving from this point and the vicinity of Charleston from May 10 on.

Youngs Island, S. C. W. C. G.

Fruit on the Delaware Peninsula.

Reports from all county vice-presidents of the Peninsula Horticultural Society show that there is at this time a fine prospect for an abundant crop of all kinds of tree fruits. Without an exception the reports state "prospect for full crop of peaches." Pears are not quite so full of buds as last year; some orchards were badly injured by blight last Summer. Strawberries did not make as many plants as usual, on account of dry weather. Raspberries were badly winterkilled, so that the crop will be very light. Some varieties of blackberries, notably the Wilson, are also injured. The season is backward, but the prospect was never better for a fine general crop of tree fruits of all kinds.

Orchard Prospects in Ohio.

The worst storm of the year commenced on April 18, with rain for 30 hours, then snow for 60 hours. The creeks were the highest known, and the rivers did immense damage. The temperature was 30 degrees above zero the coldest morning, but it did not hurt any of the fruits that I can find, although peaches and some plums were in full bloom. We have prospects of large crops of peaches, plums, apples and fair crops of small fruits. We had commenced spraying before the storm, and had to wait eight days for favorable weather and fair ground to drive over to resume the work. Apples will be in full bloom in a very short time now. Spraying is a sure preventive of fungous diseases if rightly managed. Several orchards in this vicinity will be sprayed for the first time this year. People are seeing and learning, but it is very slow. A Cincinnati commission man has bought a fine hill farm of 236 acres near here, and will raise fruits largely. The large dealers fear they will not be able to secure enough first-class stock for the demand in the near future, and some of them are going to try to raise their own supply. Where are all the skeptics who were afraid the fruit business would be overdone? Modern fruit culture demands large plantations and a manager with a large head. Are there enough of the right kind of men on the farm, or must some of the city men come back to show the farmer how to improve his opportunities? U. T. COX.

Lawrence Co., O.

Woman and Home

From Day to Day.

A CITY FARMER.

Oh, I'm a reg'lar farmer, for I got a hoe an' spade,
An' a bag of roasted peanuts, which I'm goin' to plant, you bet,
'Cause when they gets to sproutin' and has all their bushes made
They'll be loaded down with peanuts just the best was ever et!

I got a new wheelbarrow with a wheel all painted red,
An' a pair of new jean britches made up just like any man's;
An' Ma' says I'm a farmer sure enough—'at's what she said—
An' purt' soon I'll be raisin' Cain an' ripe tomato cans.

W'y, I planted lots of orange seeds just yester' afternoon,
An' a whole han'ful of raisins what had worms inside their skin;
I'm goin' to dig 'em up unless they come up mighty soon,
For I'm gettin' seared for fear they ain't stayed where I put 'em in.

Oh, I like to be a farmer an' to work out in the sun;
I'm goin' to buy a farm some day an' plant what I love best—
Of dates and figs and licorish I'll raise a million ton,
An' with oranges an' sugar plums I guess I'll plant the rest.

'Course now I'm in the city, where there ain't a bit of land
'Cept what's in our back yard, and that is where I have to play;
But we're goin' to the country, an', oh, won't it be grand?
You bet I'll be a farmer, then, an' plant most ever' day!

—Chicago Record.

*

A NOVEL idea in fancy sandwiches is to use plump little biscuits, a day old, from which the centers are removed nearly to the bottom with a sharp round apple corer, leaving a little well. This well is filled with chicken salad cut fine, and the little round crust top fitted into the biscuit like a lid. The result is a very dainty and delicious sandwich.

*

BRASS polishers in Chicago and Milwaukee have suffered from the competition of women, who have crowded into the trade, which is generally regarded as rather an unhealthful one. Instead of crowding the women out by making their surroundings unpleasant the intelligent polishers suggest finding them something better to do by encouraging matrimony, and urging the feminine operators to transfer their polishing powers to domestic life. This seems the most sensible solution of such a labor problem. To destroy competition by annexing the competitor, thus forming with her a domestic and labor trust, seems to be following the lines of great modern commercial combinations.

*

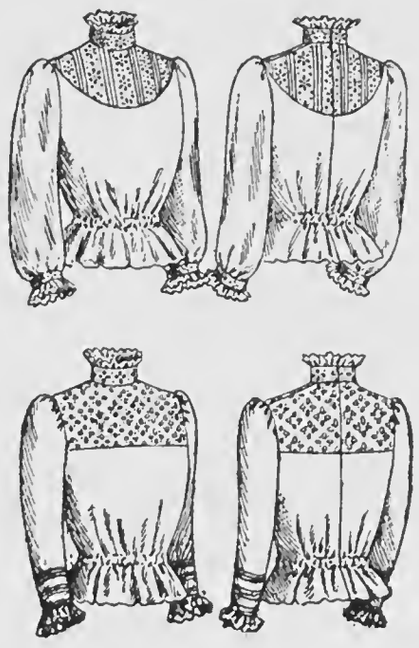
MANY of our friends who live distant from large cities have heard of the "little mothers" of New York—small girls who must daily care for their smaller brothers and sisters, and who are thus cut off by their responsibilities from the pleasures of other children. It is a common sight within the shadow of the tall building that shelters THE R. N.-Y., to see little girls of seven or eight laboriously carrying lusty babies whose weight seems enough to break the thin arms that encircle them; yet watching over their charges with the premature wisdom of experienced matrons. The little mothers cannot go on fresh-air excursions, like the other children, being as much tied down as though they had already assumed the cares of a household. Eleven years ago a kindly woman who became acquainted with some of these small girls with big burdens began to provide excursions and other pleasures for them, and from her benevolence began a movement now formed into the "Little Mothers' Aid Association," in which many influential persons are interested. The Association has bought a house in a crowded part of the city, as headquarters for the children, where instruction and amusement are provided, and where they are sure of aid and comfort in all emergencies. It is not to be called in any sense a charity, for these toiling children surely have a right to the aid and sympathy of those more fortunate, nor are its benefits limited to the narrow confines of a city. In thus strengthening the bodies and training the minds of these toil-laden little mothers, we are developing a better citizenship, whose effects are far-reaching for a better future.

*

IT is believed that the notoriety attending the recent recovery of the long-stolen portrait of the Duchess of Devonshire, by Gainsborough, will bring into vogue again the graceful curving Gainsborough hat, with its wide brim and sweeping plumes. It is very becoming to youthful faces, as, indeed, most fashions are, but it will mean the use of many feathers, instead of flowers. The Nell Gwynn hat, which is a curving cartwheel surmounted by a forest of feathers, has already made its appearance, though it is entirely too heavy for Spring wear, and indications point generally to large and picturesque shapes. They are not always easy to keep in comfortable position. Many women seem unaware that a hat is pinned more firmly when one pin is put in from each side, instead of both passing through the same way. With the pins passing from opposite sides the hat is well braced into a firm position.

*

THE shops are now so full of dainty washing fabrics that it is a little hard to remember that daintiness is not the only thing to be considered in buying the children's Summer frocks. Little folks are hard on their clothes, and it is very unwise to buy materials that must fade or grow sleazy with repeated washings. For constant wear nothing gives more satisfaction than shirting percales; they show very pretty colorings, iron nicely, and wash well to the very last rag. While most ginghams wash well, many of them fade in the sun, and they are not quite so easily ironed as the percales. A little girl's Summer



3741 Girls Guimpe,
6 to 16 years.

wardrobe should always include some dark washing frocks of heavier material, suitable for rainy days or railway journeys. Galatea is admirable for this use, and a sailor suit is the best style for making it. The domestic galatea costs from 12½ to 15 cents a yard ordinarily; imported makes are 25 cents a yard up. Both are very serviceable.

ART is long, life short, judgment difficult, opportunity fleeting. To act is easy; to think is hard; to act according to our thinking is troublesome.—Goethe.

The Rural Patterns.

Guimpes are a necessity with girls' Summer dresses. The model illustrated is available for all suitable materials, lace, tucking, all-overs of all sorts and to any fine fabric which one may prefer. As illustrated, it is of lace and needlework, and shows bishop and dress sleeves, round and square yoke, for all of which the pattern provides. The front and backs are smooth across the shoulders, and drawn down in slight gathers at the waist line. The yoke is applied as indicated, but if a transparent effect is desired, the under material can be cut away on the line of perforations and the edge finished neatly on the under side. The bishop sleeve is cut in one piece and is finished by a frill and band of needlework or lace. The dress sleeve is two-seamed and finished by a frill of the material, lace or embroidery, as preferred. The neck is finished with a standing collar and frill, and the closing is effected invisibly, or with buttons and buttonholes, at the center back. To cut this guimpe for a girl of 12 years of age 1⅝ yard of material 36 inches wide will be required, with ½ yard of all-over lace, embroidery or tucking 18 inches wide for yoke and collar. The pattern No. 3741 is cut in sizes for girls of 6, 8, 10, 12, 14 and 16 years of age; price 10 cents.

3751 Girl's Blouse Dress,
4 to 12 Years.

The simple little frock that can be worn with or without a guimpe makes one of the best possible models both for light wool and washable materials. The pretty model shown is made from mercerized madras in shades of dull blue, and is trimmed with needlework insertion and edging, but all cotton stuffs are suitable, as are cashmere, veiling, albatross and the like. The skirt is straight, finished with a hem at the lower edge, and arranged in gathers at the waist, where it is joined to the belt. The waist is simplicity itself. Both backs and fronts are gathered at the upper and lower edges, the fitted lining being used or not as preferred. Around the Pompadour-shaped neck is a flat, square collar, that is eminently becoming and which, at the same time, can be laundered with ease. The lower edge of the waist is attached to the upper edge of the belt, and the entire gown closes at the center back. The short sleeves are gathered in puffs and finished with straight bands. To cut this frock for a girl of eight years of age 4⅝ yards of material 27 inches wide, 4¼ yards 32 inches wide, or 2⅞ yards 44 inches wide, will be required. The pattern No. 3751 is cut in sizes for girls of 4, 6, 8, 10 and 12 years of age; price 10 cents.

RED LETTER DAYS.—There are days when some especially important event takes place, or when an unusual pleasure is enjoyed. I like to make more than the ordinary record of these red-letter days in my diary, so what more appropriate than that I should use carmine ink for the purpose? Sometimes only one paragraph is written in red, when there is one noteworthy incident in an otherwise uneventful day. In looking over my diary in after years, these red pages and paragraphs will stand out conspicuously, making it easier to find the more important happenings.

S. B. R.

TOO MUCH LEARNING.—It is amusing to hear people, when they are asked their opinion about what studies a boy should pursue, ask first: "What are you going to make of him? What is he going to do for a living?" They seem to think that there would be danger of his knowing too much, unless he was to choose a profession. The time a boy had to give to school might make a difference about what is the most advisable course for him to take, but is not knowledge always desirable to have, whatever a man's occupation? Is a blacksmith a poorer workman because he loves and is familiar with Scott or Shakespeare? AUNT RACHEL.

Alicia Gale's Final Choice.

"There was a long time that I did not know as I ought to ask you, Alicia." Mark Washburn looked fondly at his sweetheart. "Then I thought that if it was possible that you loved me, we could do the waiting together, and if you didn't—well, I could begin to get used to it. To think that you really do, Alicia! You don't know how hard I'll work. I've planned it all out. You see," he hesitated—"well, there's no use in our beating about the bush. There needn't be any keeping things from each other now. You know what Mother is like just as well as I do. I wouldn't ask you to live in the same house—it wouldn't be right. The other boys have tried it and it hasn't worked, and no wonder when her own daughter can't stand it. My plan is to build another house right near, with a covered passage between, and maybe a telephone. Then I could look after her almost as much as I do now and you wouldn't have to be bothered. The shop being right across the road makes it handy, too. Of course it will take some time, though I have saved up something towards it already, but I am afraid we will have to wait a year or two at least. I'm helping Hugh and he will be through college by that time. Do you think you can wait as long as that?"

"Yes," said Alicia slowly. "Unless—oh, don't look at me that way, Mark! You don't know how horrid I am, but I will tell you. I've thought about it a good deal since I began to think you liked me. You see, living off in a country place like this I never have had a chance to get acquainted with many nice men. To be sure there are the neighbors, and the boys I went to school with. Now I am sure that I like you the best of any of them. You are honest and steady and intelligent; you do your work well, and you are strong and manly. I haven't the least doubt that you are the very best man I know. But I suppose there are lots of other nice men that I don't know, now, and one of them might come along that I liked better than I do you, and then what should I do? Of course I don't mean after we are married, I'm not quite so bad as that, but while we are just engaged."

"If you found a man you liked better," Mark spoke with an effort, "I think I care enough for your happiness to be able to give you up—but I don't know. I hope I won't have to be tried that way."

A year went by, and it was July again.

Mark stood in the doorway of his blacksmith shop. He was looking over across the little lake to Mrs. Mayhew's large house on the rising ground beyond. His face was sad and anxious, and the cause of his trouble was over at that house. It was three weeks since Mrs. Madison Drake and her son Theodore had come there to board. Mrs. Drake had been a school friend of Alicia's mother, and almost at once, upon her arrival, she had sought out the girl and made much of her. Nearly every day the three were together, and lately Mark had, several times, seen the young man rowing Alicia across the lake, that being a nearer way home than to go around by the road. Over and over again the last few weeks Mark had recalled every word of what Alicia had said the day they became engaged, and as he saw how happy she seemed in Drake's company, all hope left him. What chance had he, a country blacksmith with a cantankerous mother, against this handsome, well-bred city man? He saw that the time would come when he must give Alicia up. It took all of his strong self-control to keep him from betraying his feelings to her, but thus far he had acted just as he always had done. He had even shown a friendly interest in the Drakes, and listened attentively to all Alicia had to say about them.

Mark's reverie was interrupted by the arrival of Mrs. Mayhew with one of her horses. While it was being shod she went in and visited Mrs. Washburn. As he worked, Mark's thoughts were still of Alicia. When the shoes were set he led the horse out and harnessed it into the buggy again. He was just going around the other side of the horse to finish the harnessing, when Alicia and Drake went by. For a moment he looked in her face, and then they passed on, and a little later Mrs. Mayhew came out and drove away. When Alicia parted from Drake at her own gate, she stood looking after him. When he turned into the path leading to the lake, Alicia, with a light, quick step went down the road in the direction from which she had just come. When she reached the blacksmith shop she went in, but the place was deserted. "I'll wait for him," she said. She picked up Mark's hammer and rung it on the anvil, listening to the sound. There was a smile on her thoughtful face. She was dressed in white, with blue ribbons at neck and waist, and her figure stood out strikingly against the dark background. Mark coming in paused and looked at her in surprise. She glanced up, and with a little laugh laid aside the hammer.

"I wish you would come over to-night, Mark," she said without looking at him. "There is something I want to say to you."

"I will come," he answered, and stood aside so that her white gown would not brush against him.

There was an awkward constraint between them as they sat in the sitting room that evening. Alicia did not raise her eyes from the floor and there was a pause before she began hesitatingly.

"I don't know how to say what I want to, it is hard to make you understand, but I wish you to know all about it. It is about Theodore Drake." She waited for him to speak, but he said nothing.

"The Drakes have been very kind to me, and I have seen a good deal of them. I got to know Theodore very well, and the more I saw of him the better I liked him. He is really an unusually fine man, kind, thoughtful and cultivated. She hesitated, then went on again, speaking more quickly. "You remember what I told you a long time ago about what I should do if I found a man I liked better than you. Well, the more I saw of Theodore Drake the more I despised myself. I wished at first that they had never come here. Then I thought of you and it did not seem as though I could stand it. I really tried at first not to like him, but he was so nice I could not help it, and after a time I just stopped trying. He liked me, too, though he did not act silly or anything of the kind, and his mother was lovely to me.

"Well, this afternoon I decided I must see you and have a talk with you. Theodore rowed me across the lake, and then he walked up here with me. Just as we got to your shop you stepped out from behind that horse and I looked you right in the face." At the last words Alicia raised her eyes and looked at Mark. With a little cry she started up.

"Oh, Mark! What have I done?" She looked at him in a kind of terror.

He turned away from her. "Go on," he said in a strained voice. "Don't mind me."

She went to him quickly, and laid her arm about his neck. "You don't understand, Mark," she said tremulously. "I was only thinking about my own confession and I thought you would understand from the first. Don't you see? I looked right at you as I went by, and for the first time I saw you two men together. Then I knew in a flash that you are the only man in the world for me."

He turned quickly and looked in her tear-filled eyes, then he understood.

"When are the Drakes going away?" he asked a little later.

"In two days."

"I shall be glad when they are gone."

"But Mark, it would not make any difference if they stayed forever."

"Nevertheless, I am glad they are going. You don't know—but I have been horribly jealous. What are you going to do about him?"

"Nothing," said Alicia demurely. "I told him this afternoon that I am engaged to you."

"You did?"

"Yes. And as he has been such a good friend I told him when we are to be married."

"Alicia!" he cried reproachfully.

"I know, Mark, that it was very improper to tell him before I told you, but I made him promise that he would not speak of it. I will tell you now if you would like to know."

Mark sighed. "I am afraid it will be a year yet. Hugh has needed more money than I expected, and Mother being sick last Winter. I suppose I might borrow—"

"No," said Alicia with spirit. "I'll do a good deal for you, Mark Washburn, but I won't live in a mortgaged house with you."

"That's my feeling, too, Alicia, and so I don't see as there is anything to do but wait."

"Yes, till the fourteenth of next September, my birthday, you know."

"But Alicia, we can't do it—on account of Mother."

Alicia went and stood looking down at him. "Mark," she said earnestly, "I have been thinking lately about a man who is well-to-do and who could give his wife advantages, and whose mother is very fond of me. But Mark, I would rather marry you and help you to give Hugh his education, and help take care of your mother, even if she does not like me. What is more, I cannot wait any longer than I said, and if you are not ready then, I never will forgive you."

SUSAN BROWN ROBBINS.

GROWING TOO FAST

Children growing too fast for their strength need more than their ordinary food. Scott's Emulsion of Cod-Liver Oil with Hypophosphites supplies that need. It has the power to nourish and strengthen that does not obtain in their usual food.

All sickly, delicate children, who have no definable disease, are invariably benefited by the use of Scott's Emulsion.

A fifty cent bottle will prove to be the best investment you can make.

TO obtain satisfactory results in painting, we recommend that you use Pure White Lead and Pure Linseed Oil, and employ a practical painter.

If the services of a competent painter cannot be obtained, you can get satisfactory results by using any of the brands of *Pure "old Dutch process" White Lead* named in the margin and the National Lead Company's Pure White Lead Tinting Colors, by which any shade desired can be made, the greatest economy and the most permanent satisfaction secured.

For any color or shade required, use NATIONAL LEAD COMPANY'S Pure White Lead Tinting Colors. Pamphlet sent free upon application.

BUSINESS BITS.

PREPARE now for those berries which will be ready for market in a few weeks. If you have not yet purchased baskets, write South Side Mfg. Co., Petersburg, Va., or Webster Basket Co., Webster, N. Y. Both firms are reliable, and will send you just what they agree.

FRUIT growers have realized at last that they must spray thoroughly every year in order to insure a crop. They can't afford to take chances on the occasional off years, when a crop can be grown without spraying. Spray every year is a good motto. Ross Bros., Worcester, Mass., offer a practical outfit at a reasonable price.

GRANT FERRIS CO., Troy, N. Y., make a specialty of straight-straw thrashing machines. They guarantee the machines to thrash wheat and rye perfectly clean without breaking the straw, and then bind the straw in bundles. This machine can be changed to an oat thrasher in a few minutes, and takes less floor space than other outfits. Write for Catalogue B.; address as above.

IN the past several years certain manufacturers and others, with that knowledge and unbounded faith born of experience, have been sending out all sorts of things to the farmer to be first tried by him and paid for only after he is convinced of their merit and satisfied with the bargain. So far as we know, however, the Kalamazoo Carriage & Harness Co., of Kalamazoo, Mich., is the first firm in the United States offering to send out carriages, buggies, wagons, harness, etc., on this plan. This appeals to us as being about as fair and open a method of doing business as it is possible to adopt. We have used a wagon, made by this firm, and have found it satisfactory and first class in every particular. Address as above for free catalogue.

HARD-COAL ashes is the thing to dust the roosting places to keep mites off the hens, and is just as good to keep lice off cattle.

Elkhorn, Wis. S. D. H.

WONDERFUL HENS.—On page 274 a correspondent wants a wonderful bird. Allow me to suggest that the Rhode Island Red is both useful and good to look at, good layer, and will fill the bill for an all-round fowl. The Reds make great pets, and if the old couple should choose them I feel confident they will not regret it.

Standish, Mich. D. W. R.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

Many a distressed sufferer from Lung or Throat trouble, who had lost hope under the false idea that his disease was incurable, has been restored to perfect health by Dr. D. Jayne's Expectorant.—*Adv.*

FOR SALE.

Country Home, "Rural Grounds,"

of the late ELBERT S. CARMAN, for many years owner and editor of The Rural New-Yorker.

Situated in the Hackensack valley, 18 miles from New York, one mile west of the station, River Edge, on the New Jersey and New York Railroad. House in excellent order with broad piazzas. Good stable and carriage room. The grounds, consisting of a little over two acres, are beautifully graded and planted with rare coniferous and deciduous trees and shrubs. A never-failing lake of pure spring water adds to the beauty of the grounds.

MRS. ELBERT S. CARMAN, of No. 5 West 82nd Street, New York, will answer questions and show views of the place

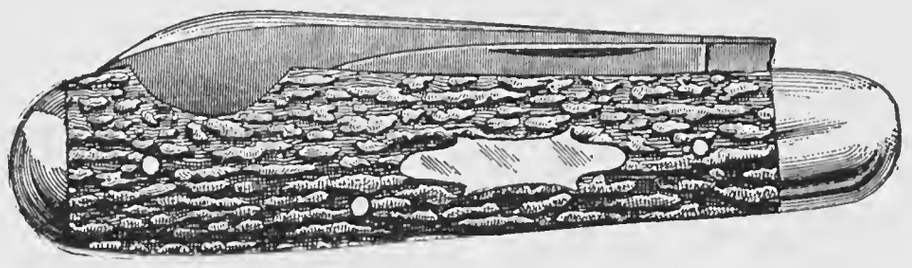
TROY CHEMICAL CO., Troy, N.Y.



Easily Opened Knife

Every farmer or mechanic wants a good strong knife in his pocket. You can never find anything better than this knife. It has two blades, hand forged from best steel. Stag-horn handle, brass lined and capped. A feature of this knife is the ease with which it can be opened because of the large purchase of the fingers on the blade. The price is $1. We send it post paid and one new yearly subscription for $1.40; or free for a club of two yearly subscriptions at $1 each.

The New Horticulture

BY H. M. STRINGFELLOW.

We do not hesitate to say that this is one of the most interesting books on horticulture that ever was printed. Most reading farmers have heard of the now famous "Stringfellow Method" of planting trees, but few understand clearly what it is. This book tells the whole story in clear cut, forcible style, which all can understand. Not only is the theory of close root-pruning carefully explained, but the general principles of gardening and fruit-growing are discussed. Mr. Stringfellow is a practical gardener, and he gives his own experience. We commend the book to all without reserve. New Edition, paper covers, 50 cents.

THE RURAL NEW-YORKER, New York.

Market Briefs.

PICKED UP HERE AND THERE.

APPLE VS. ORANGE.—From the opinions expressed by many people we judge that not more than two out of 50 really prefer an orange to a prime apple, and it is doubtful whether anyone will claim that the large, smooth, perfectly-ripened Northern Spy is equaled by any representative of the orange tribe that reaches this market. It is true that there are some oranges of extra quality which are not good shippers and are unknown to consumers in the New York market. Like certain varieties of choice Florida pineapples, they are eaten where grown, as they will not stand transportation.

COMPARATIVE PRICES.—The following is a common scale of prices of apples to small buyers: Two for one cent, one cent each, three for five cents, two for five cents, three for 10 cents, and five cents each. The two-for-a-cent grade are very small or unsound. The bulk of the oranges retailed on the streets go at two or three for five cents. Occasionally small ones are sold for one cent, but not many. The large ones go for the same price as the largest apples, five cents each. There are great quantities of inferior and mixed apples with comparatively few prime ones, while just the opposite is true of the oranges, the small and mixed lots being few.

REFORM AND ORGANIZATION.—With the present methods of growing and marketing apples it is safe to say that a bushel, or 100 bushels, of the grades retailing at five cents or two for five cannot be placed on the New York market so cheaply as the same quantity of oranges retailing at these figures, on which the cost of 3,000 miles of transportation has been paid. There are plenty of so-called apples which manage to come to maturity after a hard season's fight with soil starvation, insect pests and fungus diseases, and our markets are flooded with these scrubs, which are practically the "razorbacks" of the apple tribe. The western hog man raises corn-fed Poland Chinas because they give him more profit than "razorbacks," and the same principle should hold with five-cent apples as compared with scrubs. There are two things in particular which in part account for the place the California orange holds in eastern markets: Thorough organization among growers, and intelligent and systematic marketing. The orange men have had many difficulties, and their troubles are not all over yet by any means, but the magnitude of the trade they have worked up shows what may be done by keeping at it. Of course, the conditions in orange-growing districts are entirely different from those in the apple sections, where diversified farming is carried on to such an extent that the fruit business is secondary, and coöperation in the same lines as where hundreds of adjoining acres are producing the same kind of fruit, is impossible. Yet something of this sort must be done before apple growers can make much impression on the market with large quantities of uniformly fine fruit. But is there not an overproduction of apples? Are not the markets so crowded now that apples frequently sell for scarcely enough to pay for picking and shipping? Not of the type mentioned. Suppose a man should come here with a sample of Northern Spy, or some equally good variety, large, smooth and high-colored, and say that he had 500 bushels of just such fruit, which he would wrap, put up in suitable bushel boxes and label something after the style of California oranges; he would make a sensation, and have no trouble in interesting fruit dealers who cater to the better class of trade. Now and then some one makes a spasmodic effort, but he either does not sell to the right parties, or expects too much on the start. One grower trying to do this alone has a hard row to hoe, but suppose the majority of the large apple men in New York State, for instance, who are willing to take the trouble to raise good fruit and spend time and thought in marketing it, got together and hung together for 10 years, working with an aim to produce the best article and see that it reaches the consumers who want it, there would be no doubt about the future of their business. People here want good apples, but cannot get them. There would be plenty of opposition from retailers who are not at all anxious to handle apples in bushel packages that could be sold unbroken, on the strength of a label, to the consumer. They would much rather retail in one or two-quart lots at double the profit. Many commission merchants also would not encourage this, but there are some of the better class who would be glad to work with the grower to bring about a reform in the apple business. It is a matter of producing what is wanted and getting it to the people who want it. Unless the latter is done, there is but little use in doing the former. Here is where a mistake is being made right along. Some day apple men are going to wake up to the possibilities before them in the shape of hundreds of thousands of people in the great cities of the East who are hungry for good apples. W. W. H.

PENNSYLVANIA FRUIT PROSPECTS.

Small fruit came over Winter in a fine condition. Spraying is now in order. But very little is done throughout here, about 10 per cent only. We have no large growers of apples and pears. We have some who grow strawberries, peaches, dewberries and raspberries, but these are beginners only. J. M. G.

Liekdale.

The prospects for small fruits in this section are very promising. The trees stood the Winter well and are just beginning to bud. Peaches, pears and plums promise a good crop. Spraying is done more and more every year. Grain fields are in a very good condition, and promise a good yield. W. S. U.

Myerstown.

Small fruit came through in good condition; present outlook for trees is good. I only know of one besides myself who sprays at all. I spray just as soon as buds start and then just after blossoms fall, and find by so doing that I have fruit on trees 15 years old that have never borne good fruit until they were sprayed with Bordeaux Mixture. I am of the opinion that it is the only way to get good fruit.

North Orwell. J. P. S.

All fruit trees in our section have come through the Winter in good condition, and are starting out this Spring very nicely. One unusual feature is that the peach trees are set full of blossom buds and bid fair to bloom very fully. Peaches are very unreliable with us, and we get them only once in three or four years. Cherry and pear trees are set well with blossom buds and will bloom fully. The plum trees are a little later, and have not made much advancement yet. The apple trees are in good healthy condition. Berries and currants did not winterkill at all, but strawberries got such a poor start last Fall, owing to the very dry weather and the work of the White grub, that they are not in good condition to produce much this year. So far as I know none of our fruit men in this section sprays regularly. Some spray their small fruits, but the apples are neglected. I wish that the attention of farmers could be called to the fact that cherry and plum trees affected with black knot should be destroyed; I see many trees left after they are killed, which should be cut and burned.

Sugar Grove. R. J. W.

Weight of Grade Lambs.

We have mentioned the grade Tunis lambs which Clark Allis, of Orleans Co., N. Y., has been selling. We are now able to give the weights of some of these lambs as compared with those of other breeds.

"I send you the weights of seven Tunis grades and one Shropshire grade. The Shropshire grade was shrunk; he had been away from his mother two or three days, but had what grain he would eat, which was not much, and the Tunis were taken off full feed the morning they were killed. April 10, one Shropshire grade, wether, live weight, 58 pounds; dressed, 31½; April 10, one Tunis grade, ewe, live weight, 51 pounds; dressed, 29; April 10, one Tunis wether, live, 52 pounds; dressed, 29½; April 10, one Tunis wether, live, 52 pounds; dressed, 30½; April 12, one Tunis grade wether, live weight, 52 pounds; dressed, 29, one Tunis grade wether, live, 55 pounds; dressed, 33½; one grade ewe, live, 52 pounds; dressed, 30; one wether, live, 52 pounds; dressed, 31. This is about the way they run all through. Have dressed some at 47 to 48 pounds, live, and had them weigh 28 dressed. All of the lambs were full dressed; hide and head off, liver and lungs out. I killed a purebred Merino last week that weighed 53 pounds live and 28 dressed; his hide weighed eight pounds, also a Shropshire grade ewe 48 live, and it only dressed 25 pounds; it was good and fat."

A. H.

A JERSEY GRANGE.—We organized a Grange at this place one year ago, and now have 100 members. We run a co-operative business, and do a large trade. We meet once a week, and have very busy times. Grangers go home loaded with goods. We sell at an advance of five per cent on cost. W. M. D.

Three Bridges, N. J.

PAPER BERRY BASKETS.—For several years I have been making it my business to watch the progress that paper berry-basket manufacturers have been making, and I have yet to find one shipper of berry baskets who is willing to change from the firm, white and clean wooden berry baskets to paper baskets, that are not firm and are easily soiled. The prices of wooden berry baskets are from $2.25 to $2.50 per 1,000 for the very best, while the prices of paper baskets are about the same. They are in the knock-down shape, and it is required to fold them into a basket, the labor being worth fully $1 per 1,000. A paper basket is easily soiled, is not firm, and will not carry berries to market in good condition, while a wood basket is strong and firm, white and clean, and by long experience it is known to fruit shippers that the wooden basket will stand the carrying of berries to the most distant markets.

A. REASH.

FRUIT IN NEW YORK.—Small fruits have wintered well; conditions favorable for good crops. Seventy-five per cent of fruit growers spray 90 per cent acreage. I prefer to apply Bordeaux in early April, as leaf buds open, and just before blossoms open. No steam or gasoline sprayers are used, and only one "geared" machine.

Springtime

Is the sweetest season in human life, as it is in Nature generally. It is the time of promise. As the young girl draws near to that mysterious line "Where womanhood and girlhood meet," her whole destiny is in a measure being determined. How often the sweet young girl, under the influence of the change, withers and droops like some blighted bud. Nature generally needs some little help at this critical period, and this help in its best form is contained in Doctor Pierce's Favorite Prescription. It establishes regularity, and gives the vigor of perfect health to the womanly organs. It contains no alcohol, neither opium, cocaine, nor other narcotic.

Miss Emma Lee, of Williford, Sharp Co., Ark., writes: "I was suffering severely and tried several doctors' remedies, but received only very little relief; therefore, I feel it my duty to write and let other sufferers know what your 'Favorite Prescription' and 'Golden Medical Discovery' and 'Pleasant Pellets,' have done for me. I took eight bottles of 'Favorite Prescription' and 'Golden Medical Discovery,' six vials of the 'Pellets,' also one bottle of your 'Compound Extract of Smart-Weed.' As soon as I had taken the first bottle I could see that the medicine was helping me. I had disease of internal organs with bronchitis and catarrh. I also used the local treatment you suggested."

The sluggish liver can be cured by the use of Dr. Pierce's Pleasant Pellets.

SOILING CROPS NEEDED.

Dry Weather Ahead.

I'm not a prophet or a son of a prophet, but for about eight years in institute work I have prophesied dry weather for the dairy farmer during four to eight weeks of the Summer, and records show that I have absolutely failed but once in the time mentioned. In varying degrees dry weather comes upon us nearly every year, so much so that short pastures suffer and dry out, providing only a scanty subsistence. I feel confident of my position on this question; it is one of the things I am *sure about*. That in all sections where I have had an opportunity to study, and in northern New York, where I see things every year without color, one of the weakest points in dairy feeding is lack of green, succulent food for July and August. We talk much and write more about balanced rations, and we need it all, but it is something of a conundrum to me how much good a cow will get out of the chemistry of cattle foods when obliged to range over large fields, walking several miles a day in search of food. By the way, New York State has thousands of acres of non-tillable land, which would provide more profit to the owner were it stocked with mutton sheep, and cows kept on fewer acres with less exercise. It may not be wise to adopt a pure soiling system. It is my judgment that no one can better answer this question than each farmer for himself. Price of land, cost of labor, ability of the farmer to *manage* things, are factors, but as to the value of a semi-soiling system I take no middle ground. No matter what may be the price of land or cost of labor, not a farmer keeping cows can afford to do without some kind of supplemental food. You say this is no new thing; why not give us something new; let this old chestnut rest. But do you know that a call for hands up in institutes in sections where cows bring 75 per cent to 100 per cent of the income of the farm, will never exceed 25 per cent, and often not more than five per cent of those present who practice this system? It is coming to be a conundrum to me; farmers who practice it rarely give it up. I have in mind two farms that I have known for many years. One of them produces about twice as much from the dairy as the other. The ability of the cows to produce in both cases is not materially different. In a way both dairies are well fed. The cows freshen in both cases in the Winter and Spring. The difference, however, comes at a vital time, and after shrinkage takes place it has been my experience that it is very expensive to get the flow to increase even a small per cent. The farmer above-mentioned, who gets the smaller yield, does not provide any green forage crop until "sowed corn" is ready, which in our latitude is about September 1. At this time prices for milk products begin to advance, and I have repeatedly queried which farmer was most to be pitied, a man with all his milk in June at the very low price, or one without any when prices are high.

I have seen the milk flow at our factories nearly cut in twain by the heavy shrinkage of the hot, scorching weather of 31 days of July. This nearly always happens when prices are high. We have repeatedly tried to make good a loss of forage crop feed by a more liberal use of concentrates, but in every instance failure was recorded from the financial side of the question. The cow, unlike the horse, must have coarse, bulky food, at least two-thirds of her ration. What is the use of keeping three cows to do the work of two? Formerly our practice had been to commence this supplemental feeding from August 15 to September 1. Now our practice is to feed not later than July 4, and we find most satisfactory results therefrom. From this extra six weeks of feeding we are enabled to produce uniformly 100 pounds of milk a day; more from each 30 cows from July 1 to January 1 than when beginning the late feeding. This 100 pounds of milk has been worth for the period mentioned about $1. We have therefore $1 a day increased income from each 30 cows for six months due to six or seven weeks extra supplemental feeding. We find the $1 a day will nearly pay the whole expense of grain food for the same length of time. Then why not arrange at once to supply this want?

I do not believe yet that we have anything for the more northerly dairy sections as safe and satisfactory as oats and peas. Select some dry ground that is ready to work and sow 1¼ bushel peas plowed under four or five inches. Please do not try to harrow them in. A drill will do fairly good work if we could be assured of reasonably wet weather. I have repeatedly observed that those plowed in would maintain a growth after those covered shallow had quit. Do not hesitate, fearing you may not need the stuff—they make the best of grain and as good milk-producing hay as the average grass with its usual small per cent of clover. Our first sowing has now been in a week. The weather has been cool and wet, and the peas have not grown too much for safe sowing of the oats. I like to have them come up at the same time, if possible. It is a most difficult problem to manage. Sometimes we cannot wait more than four or five days before sowing the oats, from 1½ to two bushels to the acre. If the peas are under four to five inches, one may safely wait until they are sprouted. Of course we must not wait so long that the drilling or harrowing of the oats will disturb the growing peas. I would roll the land after sowing, if on the loamy soils, in order to hasten germination and then if dry weather is probable put the weeder on behind the roller, and compact for the seed and dust mulch for the retention of moisture with the same effort.

The great demand for Canada peas has put the price if one has to buy quite high; for two years I bought for our neighbors, and a few for our own use, 75 bushels of perfect stock at $1.07 delivered, but then, considering their many values—a protein crop for forage, a nitrogen gatherer to some extent, and a pulverizer of no mean value—we can well afford to pay the price. My father used to say: "It would pay to sow peas to fine the soil." They had the same effect then as now, only our scientific friends have in more recent years found out the why of it. In fact, the great development of agricultural science during the two decades just past has been rather the finding out the why of things than the discovery altogether of new things.

One of the men has just come in, saying: "The ground is ready, and you better come and sow the oats on the pea ground." As he is one of those men who means what he says I am going to stop writing and do something that I am *sure* will do some good to the cows when the dry weather comes on. Don't fail, dairymen, to sow this all-important crop if you have not already done so.

H. E. COOK.

SMALL COW.—I saw in THE R. N.-Y. an inquiry for a small cow. I have one four years old and she is not as large as a medium yearling. She was very small when dropped, on the first day of April, and we called her our April fool. C. MCG.

Amsterdam, N. Y.

WHY BUTTER MAY NOT PLEASE.

That butter fails to please the consumer may not always be the fault of the maker or due to the over-fastidiousness of the buyer. Two instances have recently served as an illustration. The express wagon at a rural village in a dairy region drove up to the railway station from the village office and stood waiting for the arrival of the train. On it were two or three tubs of butter, presumably consigned to private consumers. In close contact with them, doubtless consigned to some dealer in hides, was a bundle of skunk skins. If the two commodities continued their journey together, as they probably did for a time at least, the warmer and more confined air of the express car would aid in diffusing the aroma more effectively, and perhaps in adding to the satisfaction of the consumer. A man purchasing butter in considerable quantities from a distant dairyman complained that the butter was not clean; that it was even filthy, and that a layer around the outside of several tubs had to be cut off and thrown away, because covered with dirt and small sticks. The dairyman was nonplused. He knew that each tub was carefully washed and soaked before being filled, that no other person had had the handling of it. He acknowledged that in the extreme drought of the past season it was at one time necessary to draw water, which being low might have left a slight sediment, but the quantity of dirt found ruled out this explanation. The purchaser finally offered the most tangible explanation, which was that the tubs, which had been sent by freight in cold weather, had been so roughly handled that the covers were loosened and the butter rolled out upon the floor of the car or freighthouse. Neither incident is particularly encouraging to the dairyman who must depend upon a distant consumer. F. W. C.

SHOEING GEESE.—The following is taken from Notes and Queries: Three million geese are brought regularly to the October market in Warsaw, Poland. Often coming from remote provinces, many of these geese have to travel over long distances upon roads which would wear out their feet if they were not "shod." For this purpose they are driven through tar poured over the ground, and then through sand. After the operation has been repeated several times the feet of the geese become covered with a hard crust.

Ailing Animals.

ANSWERS BY DR. F. L. KILBORNE.

Suppuration in Cow's Udder.

What should I do for a cow with gathering in udder; pus runs from three of her teats? The other one is gathered and I can't get it open. She will be fresh in a few weeks. W. W. B.

Reno, Mo.

Your description indicates extensive suppuration in the udder, probably due to lack of proper attention in drying off. If such is the case she will be worth little or nothing as a milker, and you will do well to beef her after calving. The suppurating cavities should be irrigated at least once daily with a two-ounce solution of carbolic acid, or other antiseptic, to check the suppuration and favor healing.

Heifer Calf With Large Udder.

I have a heifer calf dropped January 17 which has an udder as large as a two-year-old when three months with calf. It seems to be increasing. What is the reason? A. W. B.

Groton, Mass.

There may be some disease of the udder, the nature of which can be determined only by a personal examination. If there is no disease, it is simply a case of unusual development of the udder; but why this should occur in this case I cannot answer any more satisfactorily than I could why one cow has larger easy milking teats, while another's are small and hard-milking.

Cough and Thick Wind in a Horse.

I have a young horse that had distemper a year ago, and was very sick. Since then she has coughed, and breathes badly when drawing hard or trotting. It is not what is called wh'stling, but thick breathing. Can you tell me what to do for her?

Ludlow, Vt. H. L. P.

I would advise taking the horse to a competent veterinarian for examination, to ascertain the nature of the trouble. If unable to do so, try a course of arsenic. Give one tablespoonful Fowler's solution of arsenic, in the feed once daily for three or four days, after which increase the dose to two tablespoonfuls and continue for a month or six weeks. Blister the throat from ear to ear with ammonia liniment, and repeat after three or four weeks.

Disinfectants and Their Use.

A pet cat had a bad sore, which broke, the pus from it falling about the house and woodshed. What disinfectant can be used to destroy danger of infection? What disinfectants can be used to destroy the bacilli of glanders and tuberculosis in animals? How long does danger of infection last, if horses or cattle distribute bacilli by coughing or sneezing on the passer-by?

So. Royalston, Mass. A. W. L.

For disinfecting your clothes when soiled with pus or nasal discharges, boiling water is one of the best. Allowing the clothes to remain in the boiling water for five to 10 minutes will effectually kill all ordinary disease germs. If the clothes cannot be boiled, sponge off thoroughly with a five-per cent solution of carbolic acid, after which hang in the sun to dry. For your hands and face a 1-to-1,000 solution of corrosive sublimate in water may be used. The corrosive sublimate can be obtained of your druggist in compressed tablets that will readily enable you to make a solution of the desired strength. A corrosive sublimate soap can also be obtained, that is made especially for this purpose. For hitching posts, stalls or other stable or out-of-door woodwork a solution of a half-pint of strong commercial sulphuric acid in each two gallons of water, and applied with a brush or broom, is one of the cheapest and most effective. Care must be taken not to get the acid or solution on the person and clothes. In the house scrub the floor or other woodwork with boiling water, to which chloride of lime can be added to advantage. In all these cases the disinfected articles are safe as soon as dry. Other modern disinfectants, such as sanitas, creolin, zenoleum, chloro-naptholeum, etc., can be obtained of your druggist with directions for their use in each case; but they possess no special advantages except in special cases, or in the hands of the practitioner.

PIG POINTS.—I have seen in my own herd and others whole litters that I would not sell for breeding purposes, but this is very seldom, and I have had litters of 10 of which everyone was fit for shipping. Pigs of small litters mature earlier, but I prefer a boar pig for herd leader out of a large litter. The best and most prolific sow I ever had in my herd was out of a litter of two pigs. H. A. YOST.

Camden, O.

A PLEA FOR RED POLLED CATTLE.

In THE R. N.-Y. of March 9, page 176, I find a plea for Holstein cattle by W. M. Benninger, and an article by G. G. Gibbs, on page 175, favoring the Dutch Belted cattle. Another, Edwin Hoyt, favors the native polled cattle, and last, but not least, the Hope Farm man favors the woman, Bud, Scions, etc., and perhaps the Jersey breed of cattle. Many cattlemen and some of our agricultural papers claim that a farmer should select cattle either for beef or the dairy, if he wish to succeed, or derive the greatest profit from the money invested. They may be right, but I would ask them, are there not horses, sheep, chickens, etc., classed as general-purpose kinds, that give the best of satisfaction and a good profit? Then why not a general-purpose breed of cattle? I believe the Red Polled cattle are such, and that the average farmer will succeed with them where he would fail with some or any of the special-purpose breeds. The Red Polled cattle are medium to large in size, compact, very hardy, good milkers, and their milk is of good quality; they are very gentle, uniform in color, and when crossed with other breeds about 75 per cent will show red color, and about 90 per cent will be hornless. With me the grade cows have been very good milkers and of good size.

About 14 or 15 years ago (when I began looking up their peculiarities) there were but about 800 of them in the United States, bulls, cows, heifers and calves, registered or eligible to registry, and I regret very much that I did not buy a pair of them at that time. I bought a registered bull in March, 1891, and was so pleased with his get that in May, 1895, I bought another bull and a registered cow, Ruby Twin. The cow was due to drop calf in about a month, and she was about 5½ years old at that time. She has given birth to seven calves since then (one at a time), four heifers and three bulls; has not been dry more than three to eight weeks any year. She has given 10,239 pounds of milk in a year, and when the six years are up (June 1, 1901) no doubt will have given over 60,000 pounds. The average test of her milk is about 5.2 per cent butter fat. Some may call her a freak or wonder, but we have a heifer that dropped her first calf when she was about 29 months old, that gave over 5,500 pounds of milk the first year; average test about 4.6 per cent fat. There is a herd of Red Polled cows (mostly young) owned near here, 15 or more in number, that average over 5,000 pounds of milk per year; milk that tests over four per cent butter fat. There are many good Red Polled cows now in Ohio, Illinois, Iowa, Wisconsin and other States, and many in England that would make about as good a showing at the pail as any of the special dairy breeds, and a much better showing for beef. For their beef qualities I will refer you to an article in the Breeder's Gazette of April 10, page 672, written by S. McKelvie, Clay Co., Neb., where he says that he just sold a Red Polled bull 12 months and 14 days old that weighed 1,275 pounds. S. S. C.

Waupaca Co., Wis.

A Guernsey's "Lost Pedigree."

On page 257 of THE R. N.-Y., April 6, you refer to a grand representative of the Guernsey breed, and give her illustration under the heading of a "Lost-Pedigree Guernsey," and state it would be interesting to know how the pedigree of so nice an animal was lost. I am glad to tell you, because it is an object lesson to all those who handle improved stock. The animal was raised by a man who had as a foundation some purebred registered Guernseys. While he liked his cattle he was interested in the financial side of his herd and thought that it was a needless expense to pay the small fee required for recording the animals. Consequently he made no record of the births and parentage, and the result was that after a few years he was unable to place his animals, and the consequence is a loss of many times more than the registry fee in the value of the cattle. In this one instance there would undoubtedly be paid enough to cover the entry fees of his entire herd for a number of years if the ancestry of this animal could be traced. It should be a warning to all persons who handle cattle, especially those who are handling purebred animals. The importance of registration should not be overlooked. While the mere fact of registration cannot add any stated quarts of milk or pounds of butter to the yield of the animal, it is a guarantee of the ancestry, and an index by which the desirability of the parentage can be determined. In this day of enlightened dairy farming no herd of grades or purebreds could be managed without a proper set of records, for that is the only means of determining the profitable and unprofitable animals of a herd, as well as being a breeding record. WM. H. CALDWELL.

Peterboro, N. H.

SOME CONNECTICUT HENS.—The following figures will show what our hens have done during the year 1900. We commenced with a flock of about 150. At the beginning of October 71 of this number were sold to the butcher; we keep no hens of more than two years old. The flock is a mixture of four or five different breeds, something like Hope Farm hens. Their eggs are sold every week to a grocer in Derby at two cents above market price. Every egg is warranted to be fresh, and for more than two years not a bad egg has been sold: January, 145 dozen; February, 134 dozen; March, 185 dozen; April, 220 dozen; May, 280 dozen; June, 163 dozen; July, 105 dozen; August, 99 dozen; September, 45 dozen; October, 47 dozen; November, 25 dozen; December, 76 dozen. Total, 1,334 dozen. These are exclusive of eggs used in family or in sitting, but merely an account of what was sold in market. The statement is made not to boast, but to find out whether I am keeping along with the procession.

DE LAVAL CREAM SEPARATORS.

The De Laval Cream Separators have ever been the best of separators. They were the original and have led in every stage of development. The "Alpha" disc invention is restricted by patents to the De Laval machines only. The 20TH CENTURY improvements give them still greater capacity and efficiency. They are as much superior to the best of other separators as such machines are to setting methods.

All sizes, styles and prices —$50.- to $800.-

The Efficient Hiller.
Patented Jan. 30, 1900, U. S., Feb. 5, 1901, Canada,
is a new implement for hilling Corn, Cotton, Potatoes, Tobacco or any kind of plant cultivated in rows. It can be adjusted in width to plant rows from 20 up to 40 inches apart. The peculiar formation of moldboards with extensions insures the banking of the soil close to and over the roots of plants at each side of furrow. The extensions brush the soil downward and outward, forming a uniform-shaped hill. The amount of soil desired over the roots is regulated by adjusting the wheel.
It need be drawn but once through between the rows, the earth having been previously cultivated. It is a labor-saving implement, and insures a good crop by protecting the roots of plants from heat and drying winds. Manufactured and sold by
VAN ALLEN WHITBECK, Aquetuck, N. Y.
Price $5. delivered at Ravena, West Shore R. R., Freight or Express Office, or Coyemans Landing.

THE RURAL NEW-YORKER

A JOURNAL FOR THE SUBURBAN AND COUNTRY HOME

VOL. LX. No. 2677. NEW YORK, MAY 18, 1901. $1 PER YEAR.

AN OLD ILLINOIS ORCHARD.

WHAT SPRAYING AND CULTIVATION DID.

Some Reason for Failure.

TREES ON TIMBER LAND.—The oldest apple trees in this orchard were planted about 35 years ago. Timber land was selected as, in those early days, it was supposed to be best for all kinds of fruit trees; but later experience has demonstrated the fact that just as good orchards can be grown on prairie lands, and the trees will not be so liable to the root rot. At the same time these old apple trees were set, there were also planted pear, peach and cherry orchards. The pear orchard consisted of 500 trees of the different varieties recommended for commercial use, and according to the teachings and practices of those days was immediately seeded down as a preventive of the blight. But that dread disease seemed to have a firm hold of the trees from the start, and in less than five years there was not a pear tree left that was worth saving; they were cleared out, and apple trees planted instead. The peach orchard consisted of 1,500 trees and the cherry orchard of 500. They were both thoroughly cultivated for several years, and then they were seeded down to Timothy. For a few years after seeding they continued to be profitable; some seasons turning off from one to two tons to the acre of hay, and also a fair crop of fruit. But the trees gradually ceased to bear, and died out, until in 1885 the few remaining peach trees were grubbed out and replaced by apple trees, and two years later the cherry orchard suffered the same fate. In replacing the cherry orchard a few old snags were left, where they did not interfere with the replanting of the apple trees, thinking that they might bear a few cherries for home use the following Spring; but much to the owner's surprise they have continued to live and bear good crops until the growth of the apple trees has forced their removal. A few are still living, and although they are nothing but mere outside shells or sprouts from the old stumps they have never missed bearing a good crop of fruit from that season to the present, and force the conviction that, had they been cultivated and sprayed from the start, the old cherry orchard would have been living and thriving to-day.

CROPPING THE ORCHARD.—The old original apple orchard, when first set out, was planted in small fruits, and this kind of cultivation was continued until the trees got too large, when it was seeded to Timothy. The trees continued to bear good crops for a few years after the orchard was seeded, but the fruit gradually got smaller and more worthless, until the owner concluded that they had passed their usefulness, and determined to grub them out. But it was discovered that the removal of an old, solid, well-rooted apple stump was an entirely different undertaking from the removal of those old peach and cherry stumps. It proved a slow and costly job, and not only that, but the young tree planted in its place would not start off and grow as it ought to. After spending considerable time and money in various projects it was learned that by taking a common 1½ or two-inch auger and welding a piece of iron on to the handle so as to make the whole thing about four feet long, then by boring under the stump and inserting a half-pound stick of dynamite, with about 18 inches to two feet of fuse, the whole thing could be lifted, or loosened, so that a very little extra work would remove the stump. Not only that, but it made a hole that it took a half load of fresh earth to fill up, and the young tree replanted in that place would commence and grow from the start. This proved that there need be no fear of replanting an old orchard with young trees, if dynamite were used to remove the old stumps; provided that the young trees were fed and cultivated as they ought to be. The dynamite should be 60 per cent instead of 40 per cent—that commonly used.

REVIVING OLD TREES.—In removing the unprofitable trees in one part of the old orchard it left three rows of old Winesaps in the center of a block of young trees, so that it was almost impossible to cultivate the young trees without including the old ones. It almost seemed a waste of time to leave these old trees, for they had borne no apples for six or eight years, and what little foliage they put out every Spring was small, and covered with a sooty-looking substance. Most of the trees had one or more limbs dead clear back to the main trunk, and a few were more than half gone in that way, but Spring was on us, work crowding, and their removal was deferred until we had more time. But the next Spring they came out with such a healthy set of foliage that their time limit was extended; the following season good foliage and a crop of apples, but too small for market; then two years that the crop had to be thinned in order to keep the trees from overbearing.

AZALEA AMŒNA; FLOWERS ROSE-PURPLE. FIG. 140.

SEE RURALISMS, PAGE 358.

RESULTS OF CULTIVATION.—Before this time the remainder of the old orchard had passed its prime, had long since ceased to bear any apples fit for market, and the trees would shed their leaves long before the proper time, going through half the season with bare limbs under a scorching sun, but the green hillsides of Kentucky could not show a finer set of Blue grass than grew under those same old trees. But profiting from the lesson learned from the Winesaps, it was determined to give these old trees a dose of the same treatment. The ground had not been plowed for 10 or 12 years, and the roots were only just under the surface, making it almost impossible to plow, and it was some time before a suitable implement could be found to tear up the sod without injuring too many roots. It is generally supposed that the roots of a tree extend outward about as far as the top, but the hired man in this orchard proved that was a wrong theory. Some of the long, slender roots were traced 20 to 25 feet from the main body, and the end was not reached even at that distance. These trees, like the Winesaps, did not show any of the effects of cultivation the first season, except retaining the foliage later, but the second season they came out with a healthy set of foliage that staid on all the season, and a good crop of apples.

SPRAYING EXPERIENCE.—This orchard has been sprayed for a number of years, but with such varying success at first that the owner was almost discouraged, and thought he would have to give it up. Commencing with Paris-green and water simply as an insecticide, he had gradually drifted into the use of the more complicated Bordeaux and Paris-green mixture used both at the same time as an insecticide and fungicide, for it seemed a waste of time to go through all the motions for only half the work. If you are spraying for the Apple worm why not add the Bordeaux Mixture and spray for the scab at the same time? The spraying of this orchard has had for the owner all the fascination of the game to the young gambler. The successes, to the close observer, have been just enough to show that if we only knew how and when and where to use the spray we would be masters of the situation; the outsiders have seen nothing but the failures. For several years the Early Harvest apples in this orchard had been so scabby that they did not pay the expenses of shipping; but the first season that they were sprayed with Bordeaux Mixture they were as smooth as though they had been polished. For shipment they were sorted into two grades, size being the only difference, leaving five barrels of very small but perfect apples. More for curiosity than any thought of gain the five barrels were shipped along with the others, but branded No. 3. The commission man remarked when he made his returns, that "By keeping back the small apples until he closed out the others, they sold for almost as much as the larger sizes—they were so perfect." Previous to the year 1896 the spraying of this orchard had not been very systematic as to time and number of sprayings; some years it had been sprayed just as the blossoms fell, sometimes not until the apples had formed, and then other times not until the fruit had reached considerable size, but the season of 1896 it was determined to give it a thorough spraying just as the "books" called for. A tank holding 300 gallons was made at considerable expense, and the orchard was given its first spraying before the blossoms opened, another just as they fell, another a week or 10 days later, and another one still later, with the result that during the season it showed up with a crop of the wormiest lot of apples in that section of country. The trees were full of apples and still there were not enough to furnish each worm with a home of its own. It was claimed in those days that the moth lays its eggs in the maturing blossom of the apple just as the petals fall, and as soon as the caterpillar hatches it burrows into the apple. But this orchard that season must have developed a different breed of worms, for they not only burrowed through the blossom end, but the sides as well, literally turning those apples into city flats. At gathering time those apples contained no worms, but they could not be classed as No. 1, although perfect in form, size and color, for they were bored through and through; they showed no signs of rot, just simply the holes. In examining the fruit along through the growing season, by cutting open, it was observed that

the holes were full of water and the worms dead. A neighboring grower who observed the same thing remarked that they were all drowned. Was it the downpour of rain we had just about that time, or an extra flow of juice? Almost every orchard had a crop of good fruit that year, and as this was about the only orchard in this section of country that had been sprayed and cultivated it was a great set-back to the new doctrine. It was not a failure, as the orchard turned off 1,800 bushels, but the owner was not proud of the quality.

SOME EXPLANATIONS.—The presence of so many worms that season in this orchard was due to two causes. One cause was the poor quality of the Paris-green; the other was something entirely overlooked. At the first setting of these orchards there were also planted two rows of Transcendant crab apples along the north side of the peach and cherry orchard, and when those orchards were removed the crab trees were still left. When they first commenced bearing they were very profitable, as the fruit sold well, but the price had gradually gone down until they did not pay for picking. The trees had grown very tall, so that it was almost impossible to spray them, and as they very seldom failed, and were very prolific bearers, the ground would be covered with fallen fruit. That special season they had borne an extraordinary crop, and on examination it was discovered that every little apple contained a worm, so that no matter how hard they were fought against in the remainder of the orchard this small section was keeping up the supply. These trees were chopped down and burned, and all the little crab apples were gathered up and thrown on the fire, and since then we have not been bothered with any more worms. It is astonishing how much trouble some little things will give us, and how easily they are overlooked.

ANOTHER LESSON.—The Spring of 1897 everything commenced blooming April 25, but was not in full bloom until April 29; then we had four cold, cloudy, rainy days ending with a white frost. Last blooms were gone by May 9; last four days bright, clear sun and no wind. Commenced spraying May 10, and as the previous year had been so disastrous, the spray was made stronger by adding more Bordeaux Mixture and three-eighths of a pound of Paris-green to 50 gallons of water instead of one-fourth of a pound as formerly, and each tree was sprayed until it would drip. Owing to the extra time it took to do such thorough work and also being bothered by frequent rains, we did not get through first spraying until after May 25. Shortly after that time the orchard showed up with the snarliest lop-sided lot of apples it had ever borne. It would have been hard to find a more disgusted fruit grower than the owner, almost ready to turn the whole thing out to the commons; but the Cutaway, the Acme and the smoothing harrow were kept going in that part of the orchard that had been cultivated the year before, working it up so that all through the drought of that year it had from two to three inches of dust on top, with plenty of moisture underneath. Right in the hottest and driest part of the season it was noticed that the apples on the cultivated part were improving, and they kept on swelling and getting smoother and smoother until gathering time, which resulted in an extra good crop of apples free from worms. In that part of the orchard that had not been cultivated the apples showed no improvement and were hardly worth gathering even in that exceptional year of good prices. The trees and soil were identically the same, nothing but a portable fence separating them, only one part was cultivated and the other was not. The renovation of this orchard was found to be a more serious undertaking than was at first supposed. It was five years after this work began before it gave its first crop. But since then it has never missed, and has borne six consecutive crops consisting of 1,500, 1,800, 2,700, 2,000, 3,500 and 4,000 bushels respectively. The crop of 2,000 bushels was borne in 1898, when there was not another orchard in the State that produced any fruit. H. A. A.

Neoga, Ill.

THE CARPENTER APPLE.

At the meeting of the Eastern New York Horticultural Society last year specimens of the Carpenter apple were exhibited. Nicholas Hallock, of Long Island, secured us samples of the fruit, from which the illustration, Fig. 142, was made. The originator, or shall we say "discoverer," lived at Milton, N. Y. This is what Mr. Hallock says about the original tree:

"He wants it called the Carpenter apple, for his grandson. It came up in a field of raspberries that were planted with Oldenburg and Fameuse or Snow apple. Four years ago the tree was grafted with other kinds of fruit, and pruning was neglected on the new wood. Last year the wood that was left—the original tree—bore these apples. This was the first time that it fruited, and it had 1½ bushel of apples, independent of the grafts, showing it to be a good bearer, a good grower, and a good keeper, which we know from the specimens we had at the show." We found the fruit of high quality, a good keeper and, we should judge, a decided acquisition.

CORN-GROWING IN THE CENTRAL WEST.

THE SEED BED.—To grow a good crop of corn each separate step must be intelligently taken, seed bed, seed, planting and tillage. Is not the first of these steps the most commonly neglected? A good seed bed is not made in one season. It may be finished in one season. Nature's seed bed is always in the process of making, and is ever improving. In proportion as our soil departs from the condition of a natural seed bed are we compelled to improve the character of our tools and increase our work to grow a paying crop. It is proverbial that one hardly needs to scratch a virgin soil to grow a big crop. In digging into undisturbed soil I have been surprised at its firmness. The top is covered always with a mulch; just below, the soil is half mold and is very mellow, but it quickly becomes quite firm, almost hard. Our

A ONE-SIDED ORANGE. Fig. 141.

cultivated seed beds are often hard to the very top. This is the result of exposure to the fierce sun and the beating rain, and to robbing it of humus. We pay the penalty for this abuse by buying costly machinery and multiplying labor. Would it not be cheaper to return more nearly to the conditions of the natural seed bed? Firm, not hard; mellow on top and covered with a protecting mulch.

GETTING BACK.—There is no great secret about Nature's seed bed. It is simply full of sticks and protected. In this section we save strawy manure, often in a box stall where sheep and cattle are fed in flocks. This manure is never exposed to weather, and most of the time it is thick enough to absorb the urine. It is often scattered with a fork or manure spreader on clover stubble after taking off hay or seed. Its substance is washed into the soil, and the coarser parts are thoroughly rotted, so that when preparing for corn the next season it mixes well with the soil. By shredding fodder and bedding with straw, and feed-

THE CARPENTER APPLE. Fig. 142.

ing out clover and corn on the farm, we find that the humus increases in our soil, and that it will often grow a larger crop than when new. The late growth of clover covers the ground all Fall and Winter, and takes up any nitrates that might leach out of the soil and be lost. It also prevents sudden drying in the Spring, and gives one time to break more land in good condition than if the surface were exposed. The soil has been so thoroughly shaded and mellowed that by Spring it pulverizes easily and needs little working.

FALL BREAKING.—In this latitude we do not favor Fall plowing except in tough sods. Our Winters are so open that the soil puddles too much. It is often harder to prepare the seed bed in Spring than it would be to break it and prepare it. In the Spring our date for breaking is governed more by soil conditions than by the almanac. About one season in 10 is dry early, and if breaking is deferred till the last of April the ground gets so dry that it breaks cloddy. In such seasons it is far better to break in March and harrow occasionally to conserve moisture.

PLOWING TOO WET.—It is true, however, that farmers go wrong far more often by breaking land too wet. I have often asked farmers in an institute how they judge when land is too wet. Some say that if one will squeeze it in the hand, and on opening the hand it will fall apart, it is dry enough. This is, however, entirely too severe a test. A better test is to roll it into a marble. If it will adhere when rolled you would better stop the plow. Plowing too wet will harden the seed bed, and handicap one's effort the entire Summer. It will also greatly reduce the crop. I once thought to be smart, and broke a narrow back furrow in the garden "a little too wet." Two weeks later I plowed the rest of it. The first strip worked hard and puddled into one great clod, and was hard to work, as well as made a light yield, while the later plowing worked mellow all Summer. Apply this to a field, and you have a worse result, since the garden contained more humus. Many a farmer grows a light yield of corn, and does not know that he killed his crop plowing wet in the Spring. Tramping when wet does the same thing. It makes an intelligent farmer nervous to see a drove of stock ranging across a field, when he knows that every step is bound to make a clod for the coming season.

DEEP OR SHALLOW.—Some successful corn growers plow shallow. There are some loose soils where it is better to leave the ground stirred as little as possible, but as a rule, it is far better to plow from six to eight inches deep. This is especially true on hillsides. Otherwise a heavy rain will saturate a thin seed bed and slough it down to the valley. Deep plowing exposes more dirt to the action of the air; it covers weed seed and trash deeper, and makes a deeper mulch to prevent evaporation. We have gradually abandoned the riding plows and the small walkers, and find that a large plow requiring three horses turns the soil better and crumbles it more thoroughly. We need three horses for the harrow anyhow, and they will plow half more land than two. We usually back-furrow in the Spring, and throw out in the Summer breaking. If the weather is drying we harrow up to the plow every morning to conserve moisture. If it continues dry we harrow once a week till planting time. If the season is wet the roller will puddle soil almost as hard as if not broken. It should be used with judgment in the Spring. Even if dry for a time it will puddle badly if rolled down close and soaked by a heavy rain. If Nature does not firm the seed bed, however, one must aid her with a roller. Nature's seed bed is quite firm, and if we would enjoy best results we must not have ours too loose, especially in its lower part. Nature plows her seed bed with frost and literally picks it to pieces. Since it is protected with a mulch it thaws out from below first, thus affording perfect drainage and avoiding puddling. It is protected from dashing rain and baking sun by the mulch, and from puddling by its humus. It does settle down quite firm, and contains no large air chambers and no clods. The newer part of plant roots is always covered with little hair roots, and the plant thrives best when these are all the way in touch with the soil. Openings left by careless working of the seed bed, and by tufts of grass or lumps of manure are obstructions to this contact with root growth.

AN IDEAL SEED BED is one that is too well filled with humus to puddle, and has abundant fertility. It should be so worked that if one dig up a spadeful of dirt and cast it around it will disappear, not showing clods. This bed should not settle under a horse's foot much over the shoe, and should possess a lively mellow appearance. If soil is clayey and puddles badly, it is best not to work it too fine, and to be careful to practice a rotation that will not rob it of humus. Of course good drainage is essential to growing any cultivated crop. Some one says that a good man is one that is always growing better. This is true of Nature's seed bed, and of every artificial one. Every good seed bed is one that is growing better. It is one of Nature's bounties that is given in response to good sense in management, which simply means obedience to natural law. E. H. COLLINS.

Central Indiana.

THE STORY OF A "MOTH TRAP."

We have received a number of letters from readers who wish to know about the Haseltine moth trap, which has been widely advertised. This "trap" is a pan in which stands a small kerosene lamp. Four tin reflectors are arranged so as to throw the light out. The pan is filled with water. The lamp is said to attract insects, which fly against the reflectors and fall into the pan of water. The picture shows all sorts of bugs flying about the lamp. It doesn't seem to make any difference to the inventor that many of these insects do not work at night, and are not attracted by light. He seems bound to tell a big story about his trap and so he gives unnatural habits to insects, and has them all caught! Is the trap a humbug? Perhaps the best answer to that question is found in the following statement by Prof. J. M. Stedman, of the Missouri Experiment Station:

About a year ago I tested this trap and endorsed it for the Corn or Boll-worm moth *only*. The inventor then issued circulars advertising this trap and inserted my letter all right; but he finally became bolder and bolder, and commenced to cut out parts of my letter, especially the part restricting it to the Corn or Boll-worm moth, until finally, in later circulars, he made it appear as though I endorsed the trap for all the insects he mentioned. He finally issued circulars stating that the trap will catch the Codling moth, "the insect that stings the fruit," borers, Plum curculio, Potato beetles, Tomato worm moth, etc., and just below this absurd list states that it is "Endorsed by Prof. Stedman, of the Missouri Agricultural College," omitting my letter entirely, and making it appear that I endorse the trap for the entire list of absurdities, which is false, unjust, misleading and deceptive. These circulars are being widely distributed, and his agents are selling immense numbers of these traps, no doubt largely because of the false and deceptive way in which he uses my name. Whenever a person knows better than to believe his statements in regard to the catching the Codling moth, etc., by lights or trap lanterns, or whenever they mistrust something is wrong, they write to me, and I always inform them properly, but, nevertheless, most people do not take the trouble to write to me, and as a result thousands of your people are no doubt being deceived by this humbug.

We all know that certain insects are attracted by lights. No doubt this so-called "trap" will catch many of these light-loving pests, but some of the claims made for it are preposterous.

FARMING IN THE MOUNTAINS.

THE R. N.-Y. has a big family—scattered all over this great country. Those who live in the flat valleys know little of life on the high hills. One of our readers in Colorado sends us the picture shown at Fig. 143 and says:

I mail a photograph of our mountain ranch with a few of our bossies; our altitude is nearly 8,000 feet, so you may imagine we breathe pure air. We miss the fruit we can't raise, and it makes our mouth water to read of the good things the Hope Farm people eat. C. L. R.

Golden, Col.

It would take a good many bushels of pure air to make up for the lack of good apples and small fruit. Still, there are many mountain farm homes as happy as any to be found in the valley.

AN ACRE OF TOMATOES.

As the ground was full of Quack grass we plowed it early in the Spring, and then it was cultivated thoroughly in order to get rid of the Quack grass before time to set out the plants arrived. The ground was marked out four feet each way, and then the furrows were run out one way for the plants. When the plants were being set out I noticed there were plenty of cutworms, and when I went out to see how the plants were the next morning after planting, I was not surprised to find many of them cut off. I felt pretty blue over it, but as we had more plants we reset what were destroyed. In digging out the old roots we found from four to six nice fat cutworms; it is safe to say that they did not get a chance to do any more damage. After resetting all that were out we took unleached hard-wood ashes and put a good handful around each plant, so that the cutworms would have to crawl through the ashes in order to get at it. I do not know whether it was the ashes or not, but after we put them on we lost but few plants. The worms were there, for on digging around the plant we could get as many as six or seven. Did the ashes prevent the cutworms working or not ? Do any of your readers know anything about it?

We started cultivating plants second day after setting, and though the weather was very dry, they kept growing finely. The cultivator was run through them each way once a week until they got so big that there was not room for the horse to walk without stepping on them. We could not find a bit of the Quack grass at last cultivation. The first ripe tomatoes were picked about July 25, and on August 11 we began delivering to the canning factory, and we took the last to the factory October 17, having in the meantime delivered 384½ bushels for which they paid 20 cents per bushel, amounting to $76.90. They also paid us $2.13 as premium extra on tomatoes delivered before September 1. Then I sold 20 bushels to the Italians at 25 cents per bushel, $5, making in all a total of $84.03. Beside this amount we sold a great many pounds to the Italians at one cent per pound, of which a separate account was not kept. The varieties grown were Royal Red and Michigan Red Apple. The total cash outlay was $5. J. B.

Fenton, N. Y.

LATE SEEDING OF CLOVER.

A member of our board of trustees, whose farm was in North Andover, in this State, made it his uniform practice to prepare land for seeding as late in the Fall as it could be worked, and then to put on the seed (mixed grass and clover) just before he considered the ground likely to freeze for the Winter. He stated that he got better results through seeding in this way than in any other that he had ever tried. In his practice it was not expected that the seed would start to grow at all until the following Spring. I have on one occasion tried this plan, but on the estate belonging to the College it appears to me impracticable, chiefly because most of our fields slope sufficiently so that if the land be smoothed as for grass and left uncovered through the Winter there will almost invariably be serious washing, either during the Winter, when we are liable to have thaws, or early in the Spring while the frost is coming out. I conclude that there are few localities in our State where this plan would be practicable.

Practically all seeding in this section is done in the standing corn the latter part of July or very early in August, i. e., at the time of the last cultivation, and grass and clover seeds are sown together at that time. Clover sown then becomes sufficiently well rooted so that it goes through our very trying Winters and Springs successfully, even on soils which are very heavy and retentive of moisture. This plan gives us far better results than any other we have ever tried. The field, it is true, is not quite as smooth as it could be made by replowing, but by level culture of corn in drills it is sufficiently smooth for all practical purposes. It is the practice to roll in the Spring to break down the corn stubble, and to help level such inequalities in surface as exist. Wherever corn is grown for the silo it is preferable to seed in this rather than in a crop which is to be stooked and husked, for in case the crop is stooked grass and clover are likely to be somewhat killed where the stooks stand, and these spots must be reseeded. By seeding in the manner which I have indicated we get full crops and heavy yields the first year, for both clover and grass become thoroughly well established before cold weather. If the grass is sown later and the clover during the Winter or in early Spring, the crops of the first year are never as heavy as under the plan which we follow. [Prof.] W. P. BROOKS.

Massachusetts Agl. College.

A ONE-SIDED ORANGE.

The orange shown in Fig. 142 has an abnormal development of one of the carpels or divisions of the primitive ovary. The line of division is very plainly marked between the enlarged and normal portions. The reason why one division grew so much more vigorously is, of course, obscure. We may assume that irritation of the primary cells of this particular carpel by a different pollen could have been an exciting cause, though it is often denied that foreign pollen affects any part of the fruit except the seed germ. Each pollen granule contains two active cells; one unites with and fertilizes a seed ovule, but the action of the other has not yet been accounted for, though it is surmised that its vital force may be expended at times in affecting other portions of the fruit. There are other sources of irritation which also give a possible explanation. The various orange species have been profoundly altered by long cultivation from the original bitter, waxy berries, and many extraordinary

ON A COLORADO MOUNTAIN RANCH. FIG. 143.

forms occur from time to time. The oddest is probably the Fingered citron, a sort of lemon, in which the individual carpels are separated and prolonged into a monstrous representation of the human hand. It is a Japanese curiosity scarcely known in this country, and of little practical value. The very valuable Navel orange, now almost monopolizing the markets, is really an abnormal seedless form, with adventitious cells near the tip imitating a smaller orange partly inclosed in the main fruit. The original tree grew near Pernambuco, Brazil. It was brought to the United States nearly 20 years ago, and is now perhaps more propagated than any other variety.

EVERYBODY'S GARDEN.

COMBINATION TOOLS.—The best of tools and plenty of them are, of course, much to be desired; but this involves an outlay which all cannot afford. Much expense may be saved by the purchase of combined tools, of which there are now many kinds advertised in these columns. A careful study of such tools will suggest many ways of adapting them to save time and labor. Thoroughly to understand the tool means to be able to take advantage of every condition and every possible combination, and turn them to the best account. The operator who is able to do this will accomplish more and better work than can two men who know nothing of the implement they are attempting to use; for illustration, a double-wheel hoe with rake, cultivator and plow attachments is used by me for many kinds of work. The plows set together are used for opening trenches for planting potatoes and all kinds of seed dropped closely or in drills; with the mold boards reversed and set apart the seed is nicely covered as rapidly as a man cares to walk. The hoes may be used set closely together, or apart for working between or astride the rows, and the weeds go down fast or slow, according as your pace is. A very useful attachment and one quickly made is a weeder. Take a board one inch by three feet long, drive a row of wire spikes, size 40, four inches apart, and one inch in from each edge, driving second row so as to break joints with the first. Attach this to underside of wheel hoe with two small bolts, and you have a hand weeder that will work wonders in the garden. The stroke is too wide to push the implement easily; but it may be pulled after the operator, by the handles, weighting, if necessary to work deeper. A shorter one, say 18 inches long, is very useful for work between the rows when plants are too high safely to go over them; this width may be pushed the same as the ordinary attachments, and either one serves a two-fold purpose, destroying all weeds, and leaving a fine dust mulch to conserve moisture.

SUCCESSIONS OF PEAS.—At this writing the first early and medium sorts will be well under way; but successions for late Summer and early Autumn may be sown at intervals of two weeks up to July 1. For these later crops sow the extra early varieties which mature in 50 to 60 days from germination. Choose moist and cool ground for late planting, and use plenty of well-rotted manure. The finest crop of peas the writer has ever grown was sown on sandy soil with a heavy dressing of hen manure deeply spaded in. The peas were sown in double rows, with stakes between set six feet apart. When the first tendrils began to appear twine was run along the row with a turn around each stake. As the vines grew more strings were put on a few inches apart. This holds them well in place, is more economical than brush, and is entirely practical for quite large areas.

TRANSPLANTING.—Much loss of time and plants will be saved if the work of transplanting is properly done; and the first essential to this work is in thoroughly fitting the ground. For a day or two previous to setting out the plants should be copiously watered and should never be pulled, but taken up in blocks, with as much wet soil adhering as possible. The setting should always be done on freshly worked ground, and with these precautions may be safely done even in quite dry weather without the trouble of watering out. The tops of beets, mangels, cabbage, cauliflower, celery and tomatoes should be cut back, as they draw heavily upon the vitality, which ought to go to the roots. The dibber, trowel and spade all have their advocates; but whatever the method it pays to do the work without slighting.

BEAN BLIGHT AND RUST.—These are common enemies of the Bean family, and as prevention is far cheaper than the cure it is safest to keep well ahead of these diseases. Danger from blight may be nearly or quite obviated by a liberal use of Bordeaux Mixture if taken in time. The Mixture may be safely used full strength, omitting the arsenites. Saltpeter and water in the proportion of one ounce to the gallon is a preventive of rust, and if plentifully applied to the foliage and about the roots will give a luxuriant growth. These remedies are, of course, most easily applied with the sprayer, but lacking this apply with watering pot, or whisk broom; anyway, only do not omit it. High authorities estimate that $3,000,000 damage is annually done to crops in the United States by insects, fungi and blight. Most of this immense loss can be avoided by the judicious and persistent use of the appliances now at hand, such as sprayers, fumigators, insecticides and fungicides now thoroughly tested and known to be effectual. Outfits to suit all pocketbooks and conditions are available, and their use should become general.

LIMING THE SEED BED.—For the late cabbage and cauliflower plants it is well to apply a liberal amount of air-slaked lime, thoroughly working it into the ground before sowing the seed; as it destroys worms and is a safeguard against club-root. Be sure of strong vitality in the seed, and do not make the bed where any suspicion of club-root exists. Some successful growers, instead of sowing the seed in beds, plant it where the crop is to grow; four or five seeds to the hill, covering lightly and thinning out after the plants are well established. This method saves the labor and risk of transplanting, as also the delay frequently consequent upon lack of rain, just when one is ready for the work. Personal experiments with this method have not been satisfactory, as the plants were destroyed by the Cabbage flea about as fast as they appeared above ground. In many localities where the flea has become a pest its ravages have been entirely overcome by sowing the seed in large, shallow boxes set on posts six or seven feet high. "Prove all things; hold fast that which is good," is always safe advice, and sure to lead right in the end. J. E. MORSE.

Michigan.

Cement Cistern for Manure.

W. B. W., New York.—I am going to build a small stable for two or three horses and one cow, and wish to fix a manure shed alongside with a cement floor, so as to save all the manure under cover, with a vat underneath to collect all the urine, to be pumped over the pile. No cellar under the stable. Who can tell me best how to do it? I got the idea from page 34 of your January 19 issue.

ANS.—Who can give experience with a plan of this sort? We have seen something of the sort—a cement vat or cellar under the pile of manure so that the liquids drained into it. A bucket pump was used to lift the liquids so that they leached through the manure several times, and were at last carried in a tank on wheels and sprinkled over grass or grain. The plan has probably been tried by some of our readers, and we shall be glad to hear from them about it.

Wide-Tired Wheel Hoe Wanted.

A., Dover, N. H.—Do you know of any maker of wheel plows or wheel hoes with wide tires? I work in a mill, but cultivate about three-quarters of an acre, mostly fruit, for family use and pleasure, but there is not so much pleasure as hard work when the wheel sinks up to the hub in my sandy soil, and it has to be pushed through the soil instead of over it. I would also like a wheelbarrow with a wide tire, the tire to be convex to enable it to tip sideways easily. A six-inch tire would suit my wants; would not cut up my lawn, and I think it would wheel much easier over the soil in garden. I bought an Empire spray pump last Spring, fitted it up with 50 gallons of homemade Bordeaux Mixture, and had the old trouble with narrow tires. Three of us hauled it over the garden, and it was enough for a horse, but I have no horse, so only fill it one-third full.

ANS.—Here is a chance for some of our manufacturers. Some people advocate wide tires on the hard road, but think narrow tires good enough for the soft garden and farm.

Value of Sweet Clover.

S. G. M. T., Zaliski, O.—Is Sweet clover of any benefit to the farmer? Bee papers and bee keepers are trying to get it to growing all over the country, claiming that it makes good pasture for all kinds of stock and good hay, as well as being a great honey plant. I don't see anything in the farm papers about it. I have never had any experience with it, but would like to know something about it. I am not a bee keeper.

ANS.—This is a sort of tramp and pioneer plant combined. Every country boy knows it as a settler on sand banks, along railway cuts and on bare roadsides. In the Middle West it is everywhere. Curious that it has never impressed the eastern farmer with a feeling that it is valuable as a forage plant or a soil regenerator. In the sandy lands of the South, it is used as a green manure. In the same country, where they use the "beggar weed" for the purpose of putting nitrogen and humus into the soil, Sweet clover, or Bokhara clover as it is sometimes called, is also employed. It is a biennial. If sown in the Spring some plants seed the same season, but generally they do not give a crop of seed until the second year. It is a moderately deep-rooting plant, but does not penetrate the soil as deeply as Alfalfa. As a forage plant it must be handled rather carefully, because the stems soon get hard, fibrous and unpalatable. Cattle do not take to it readily, but may acquire a taste for it. Prof. Roberts says the acquiring process is a slow one. As a cover crop it is not ideal, because it is a branchy grower and makes a thin cover. Perhaps if mixed with something else which would thicken up at the base, it would be desirable. I do not believe that we have use for it generally, except on the thinnest and poorest of soils, but on worn-out limestone soils I am of the opinion that Sweet clover is one of those plants that have been overlooked. I wish we might have some experience from those who have tried it. JOHN CRAIG.

Injured Sugar Maple Trees.

E. B. D., Brushton, N. Y.—What can I do for a maple sugar bush of about 300 trees, from which bark was all blazed off when tapped this Spring? It was done by a man who had seen the rough bark smoothed off large rough-barked trees. Mine are all small smooth ones. The spots vary from the size of a silver dollar to three inches square. Would painting do any good?

ANS.—Rossing off the bark when tapping is a most useless as well as injurious practice. It is much more harmful on thin, fine-meshed bark than on trees having coarse, scraggly bark. If rossed down to the "quick," as it very likely was in this case, a long crack, or seam will soon appear in the bark both above and below the tap-hole, and the bark will also loosen from about the hole to the extent that the rossing was done. This will certainly injure the tree, but will not kill it unless followed year after year. Simply painting over the injured place is hardly sufficient. The hole should be stopped to prevent the bark from loosening about it. Seal up the hole with a small wad of grafting wax and then apply thick paint over all. A cheap wax can be made by melting up about five pounds of rosin and one pound of tallow. This will make a hard wax that should be melted in a small cup or basin and applied with a little wooden paddle. A. R. PHILLIPS.

Land Too Sour for Clover

C. N. R., Canton, Pa.—To raise clover successfully I have to use lime. To raise other crops, like potatoes and cereals, I need potash and phosphoric acid. I use muriate of potash and dissolved rock. From my experience and what I read I am convinced that these last-named substances drive the lime out of the soil, and in other ways cause the land to become sour, or in a condition where more lime must be used in order to grow clover again. I have very little stable manure, and so hardly know what to do. It seems foolish to buy fertilizers that will put ground in such a condition that one must go to more and greater expense in applying lime before clover can be raised, and all this for the small benefit derived from the fertilizers above their cost. Yet I feel I must have the fertilizers, and so it leaves a very perplexing question. Are there other substances I could use that would not tend to sour the soil, and if so, would not their cost prohibit their use in general farming?

ANS.—On some heavy soils, especially where there is a close hardpan near the surface, it is likely that muriate of potash does "sour" the soil. Experiments have shown that on such soils lime gives excellent results. Acid or dissolved phosphate rock, as is well-known, will increase the acidity in most soils—especially those naturally inclined to be sour. Sulphate of potash or wood ashes will not cause this trouble—neither will fine ground bone. We think that the danger to the clover is exaggerated. Surely lime is cheaper than fertilizers, and in the case mentioned we should think it would pay to use 1,600 to 2,000 pounds per acre every few years. This application would prevent too much souring. You ought to read the bulletins issued by the Rhode Island Exp. Station, Kingston, R. I.

White Minorca Fowls.

What are the merits and demerits of the White Minorca fowl? READER.

The White Minorcas, as a breed, have only been known among us about 15 years. Their origin is "veiled in oblivion," but their name would suggest the Island of Minorca, in the Mediterranean, and it is claimed that they are the only Mediterranean fowl whose weight approaches the Wyandottes, averaging about a half-pound less. For a description of the appearance of the bird, will quote from the Poultry Monthly:

The White Minorca has a large body, and stands well up on its legs; it has a broad chest, and a long flat back. The standard requires the tail to be carried upright, but breeders generally prefer having it carried well back. The body of the male is long, square in front, tapering toward the rear. The thighs are stout; shanks medium in length, stout in bone, and are pinkish white in color; the comb is single, large, perfectly straight, evenly serrated, and extending well back over the head. Wattles are thin and pendulous, and correspond with the size of the comb; ear-lobes pure white. The general appearance of the females in body is the same as the male, rather long, broad and deep. Her comb is single, large and drooping to one side. The color of the White Minorca must be white throughout, feathers other than white disqualify. The comb, face and wattles are a bright red, showing no white in the face. The eyes are hazel or red.

When dressed for market these birds, with their gray legs and pinky white skin, make a poor display as compared with the yellow legs and rich golden-tinted flesh of the White Wyandotte. But, on the other hand, the White Minorca eggs are as large, beautiful, porcelain-like white, while the White Wyandottes, though a good size, are brown in color. Regarding prolific egg yield the Minorca fanciers claim precedence for their fowls, as do also the Wyandotte breeders for theirs. Regarding hardiness and early maturity, for the same reason, it seems to be a "drawn game," though I am inclined to think that the White Wyandottes have a slight advantage here, as well as in the weight and market points. While the size and appearance of the White Minorca eggs are superior, they average in weight 15 per cent more than the Black Minorcas. The birds are exceptionally intelligent, biddable and gentle. The standard weight for these fowls is eight pounds for a cock; 6½ pounds for a cockerel and a hen, 5½ pounds for a pullet. F. E. W.

Chazy, N. Y.

KENTUCKY FRUIT.—Fruit trees of all kinds are very full of bloom. In order to secure a nice marketable fruit a great amount of thinning out will have to be done. I use a device which is very simple, yet one person can do so much in one day as five can by hand. Take a stick any length (an old broom handle is good), drive a small wire nail through one end, then with a pair of pinchers bend a small hook. Commence thinning when fruit is the size of a large pea. Slip the hook over the fruit; a small jerk does the work. With a little experience the fruit can be pulled off very rapidly with no injury to the trees.

PAINT SAVES MONEY. It protects your property and improves its appearance. Buildings kept well painted last longer; without protection from weather and sun they will soon decay.

In painting, labor is two thirds of the cost. It is a waste of money to put anything but the best paint on your buildings.

The best paint is Pure White Lead (see list of brands which are genuine) and Pure Linseed Oil. This will protect your buildings longer and better than any other known paint material.

For any color or shade required, use NATIONAL LEAD COMPANY'S Pure White Lead Tinting Colors. Pamphlet sent free upon application.

National Lead Co., 100 William Street, New York.

Spraying Pays if you have the right pump

With or Without Truck.

Our No. 305 Outfit is as good a pump as ever was sold, and you will be surprised when you learn the price. We sell Pump, Barrel, 5 feet of Hose, Graduated Nozzle, which throws a spray as fine as mist, Extension Pipe for high trees and with first order from every town, 10 lbs. of Paris-Green free. Write for 100-page Catalog. free, telling all about it, and how and when to spray. Also other valuable information.
ROSS BROS., Front Street, Worcester, Mass.

Melons

in Florida and Georgia are very profitable crops if produced early in the season. The best fertilizer to force their early growth and maturity is

Nitrate of Soda,

which should be used with the proper proportions of potash salts and acid phosphate. When properly applied it cannot fail to develop the largest and finest yields for the early market.

Full particulars free upon application to **John A. Myers,** 12-O John St., New York City. *Nitrate of Soda for sale by dealers*; we send you a list of them.

The Cornell Reading Course.

Edited by John Craig, Professor of University Extension, and Editor Farmers' Reading Course, Cornell University, Ithaca, N. Y.

Grape Queries.

1. What about Campbell's Early grape? 2. How do nurserymen propagate grapes? 3. What tree would you advise growing for grape posts? J. H. L.

Benton Harbor, Mich.

1. Campbell's Early is, I believe, a valuable grape. It is a fair grower, the fruit is of good quality, and, so far as we know, the blossom is fertile. I believe it will, to some extent, replace Moore's Early. McPike is a seedling of Worden. It is larger in fruit than its parent, about as vigorous a grower, and, so far as I have been able to observe, a satisfactory bearer. It is earlier than Worden. 2. Commercial grape growers make their cuttings in the Fall. They usually cut all wood to three eyes. The cuttings are bunched, butts all at one end, into bundles containing 100 cuttings each. These bundles are pitted in the ground, butts up, in the Fall. The pits are protected from frost with manure and soil. In Spring the covering is taken off, with the exception of two inches of soil, which is raked smooth like a seed bed. The sun warms the surface soil and induces callusing. When this takes place, the cuttings are set out. 3. I am of the opinion that you could grow Catalpa very satisfactorily at Benton Harbor, and perhaps more quickly than any other timber for the purpose you desire it. You can buy seedlings from western nurserymen quite cheaply. The trees should be planted closely, 4x4 or 5x5 feet apart, so that they will run up straight. By using this tree you ought to be able to get grape posts in six or seven years on cultivated ground.

Apple Orchard; Choosing Varieties.

I am thinking of setting out about five acres of apple trees this Spring, but have not decided upon the varieties. What varieties do you advise to set out? Do you consider it a good plan to set all to one variety; or, is it better to mix them in with others on account of more perfect fertilization of the flower? C. A. S.

Batavia, N. Y.

The variety question is a difficult one. A man must settle it largely for himself. There are two general types of varieties, and perhaps two types of fruit growers. There is the fruit which is standard. This variety must be hardy, productive, carry well, fairly attractive in appearance, but the quality need not be high. This is the general market or commercial type of fruit. In apples we see examples of it in Baldwin, Greening and Ben Davis. These fruits are staples, go to the general market, and there is always a more or less regular demand. The other type of fruit is that in which quality and handsome appearance are the predominant characters. As a rule these fruits are more difficult to grow. If they were not, every one would grow them. In apples we might say that McIntosh, Newtown Pippin and Sutton Beauty were examples of this second class. Now, if a man wants to grow fruit for a high-grade market this is the type of fruit he should plant, but he ought not to plant those varieties, so particular in their requirements, and so susceptible to the attacks of enemies, unless he is prepared to give them all the care they need. My own inclination would be to set out an orchard of Baldwin and Spy and top-graft these wholly or partly with such other varieties as I cared to include. My collection would take in McIntosh, Ontario, Rome Beauty, Sutton Beauty, King and probably Newtown Pippin, the last for experiment. I would not plant in blocks. Most varieties of apples are at least partially self-fertile, but all varieties are benefited by interpollination, which may be secured by planting two rows of another and so on through the orchard. Some attention should be given to the blooming period of each. For instance, Spy is notably late, while Astrachan and Duchess are among the earliest to blossom. A late and an early variety should not be planted in contiguous rows. Cornell Experiment Station has issued a bulletin on the pollination of fruit trees, which may be had on application.

Seeding with Clover Expensive.

I am living on a hill farm, 106 acres, and have felt the dry Summers very much. Can we afford to pay the present prices for clover seed and only receive benefit from it for one or two years? A. B. M.

Coventryville, N. Y.

It does look like wasting money—just on the face of it—to purchase expensive clover seed, get a poor catch and then have it last only two years. Unfortunately we can't change the habit of the plant. It is a biennial, and goes out naturally at the end of the second year. Usually a certain amount of self-seeding takes place, and sometimes a few plants live over till the third year, so that it does not disappear entirely if we give it a chance to flower and form seed. Clover costs from 12 to 16 cents a pound at the present time. This means that it costs us approximately $1.50 per acre for seed. When a man has 15 or 20 acres to seed down it amounts to quite a sum; still, I don't think that there is any cheaper form of manure than that secured by investing $1.50 in clover seed. The catch must be a very poor one indeed that will return you less than this amount in humus and nitrogen. The fact of the matter is we northern farmers can't get along without it. We need it in balancing up our cattle ration; we should have it in our pasture, and as a soil restorative it is all powerful. Clover first by all means, chemicals if we must.

Two Connecticut Farm Hands.

HARD LINES.—I notice a recent article entitled "Wanted, an Ideal Farm Hand," in THE R. N.-Y. I would say, "Wanted (in Connecticut), an ideal farmer." A New York man went to work for a Connecticut farmer. He was to have his house rent, wood and $25 a month. After he had been there a short time the farmer refused him the wood, refused to pay him his wages, and told him he thought he ought to pay his employer for the privilege of working for him! There were 17 head of stock to be watered twice a day; the water had to be brought from the brook, quite a distance from the barn in a barrel, and carried by the pailful to the creatures; cornstalks, cut with a hand cutter, three times a day into a trough, watered down; apple pomace fed three times a day from silo; some grain was fed. All barn work had to be done, besides milking eight cows. He was up at half-past four in the morning, and worked until half-past eight or nine in the evening. Just time enough to eat his meals; had no time to cut even his firewood; plenty of odd jobs outside of the barn. He was so disgusted that if he had not married a Connecticut girl he would have made a run for York State.

E. H. K.

R. N.-Y.—From the time of Jacob, and even before, farmers have been glad to toil for "the farm girl."

AN EXPERT TALKS.—I have read the article on page 267, "Wanted, an Ideal Farm Hand," with much interest, as I do all that is printed in THE R. N.-Y. I am a farm hand myself. I think our friend, Michigan Farmer, wants too much for the wages. Of course, I am not acquainted with the scale of wages in Michigan. There is great difference in farm hands, also in employers. To some farm hands a small raise in wages will be appreciated, and the amount more work they will do will justify the raise. I have worked on a farm for others more or less for 10 years, except one year I rented for myself, but owing to my wife's health and climatic conditions, had to give it up. I have always had a few dollars per month more than others. I can always find good places to work. At present I am getting $35 per month, house rent, garden, milk, etc. I have been here over a year. I always go on with the work as if it were my own. One fault with help is they never try to please those they are working for. I have had some such help. Perhaps you will say: "Why don't you work for yourself?" I intend to as soon as circumstances will permit. Many a young man working for others gets discouraged, and don't care, for he may have to eat at a table alone, sleep on soap boxes and straw (as I have done), get up at 3.30, 4 and 4.30 A. M., and work until 7 or 7.30 P. M., and later, and on Sundays will have some pigpen to clean and repair, or calfpen to clean out, and such odd jobs. Is there any wonder that farm hands don't care and soldier? I once worked for a man who, when I hired out, said: "I want a man to work, not to soldier." That was one of the best places I ever worked. Farmers must have system and a time for work and a time for rest. M. H.

Some Ohio Notes.

Why did you not advise—page 311—that Connecticut man to sow beardless barley for hay? It is in every way superior to oats, millet, or any other annual grass or grain. The Clark method? Well, I don't know; we disked and disked, dragged and dragged, harrowed and harrowed last July, August and September, on a two-acre stubble plot, then we sowed the seed. In early April we disked the bare land over again, and drilled in 1¾ bushel of beardless barley per acre. "Ideal conditions all around" just fits the case; these conditions were absent last Fall and Winter. I think it was George Scott who told me of an editor of a farm paper who spent a day or two with him about two years ago. George said that this editor spoke about some hog-pens he had seen in Ohio, and the editor said these pens each contained as much tertility as a great many 10-acre fields in New Jersey. We are certainly wasteful of manures on our rich lands.

Second paragraph, page 312: As the Assistant Secretary of Agriculture is a warm personal friend I think I will write him to send me a new pipe; I lost mine to-day. Of all humbugs the sending out of seed labeled "selected variety" is the worst. I want to do my own selecting. Yes, sir, a hen will make lots of eggs out of cow peas. The best laying flock I saw in the past Fall and Winter had access to half an acre of cow peas which were left on the ground. C. D. LYON.

FOR OLD AGE

To the old, as to babies, the even balance of health is more important than anything else in the world. The possible health, in age, is not high and strong; it is only even.

There is no end, but death, to the trouble that comes of its loss. It ought to be watched like a baby's.

Scott's emulsion of cod-liver oil for very old and very young—in different ways—is the food to secure this even health.

We'll send you a little to try, if you like.

BINDER TWINE

It affords us great pleasure to quote prices for our famous and well-known grades of binder twine as follows:
Pure White Sisal, 8c per lb. Standard, 8c per lb. Manila, 9¼c per lb.
These prices are for any quantity not less than a 50-pound bale, free on board cars Chicago, and are not subject to discount. TERMS:—Cash to accompany order.
The above twines are our unexcelled "SMYTH" BRAND, pronounced by all who have heretofore used them to be the best in the world. They are prepared with special care from first quality selected hemp, every ball being separately tested for evenness and tensile strength and insect prepared before being allowed to pass examination, hence it is absolutely perfect, is reputed the very best binder twine in the market and we believe it to be worth 2c per pound more than any other binder twine in the market.
WE GUARANTEE our customers against any change in our price and if we go lower, you will be refunded the difference in price. We treat all our customers alike and the early buyer is afforded as much protection as the late one.
SAMPLES FREE. We guarantee our twine, every pound of it, and we will refund your money instantly and without a question if it fails to come up to our representation either in quality or count, but if you prefer to see samples before ordering, then write to us and we will send samples by return mail so that you can see and test it.
JOHN M. SMYTH CO. 150-166 and 287-289 W. MADISON ST. CHICAGO, ILL.

Ruralisms

NOTES FROM THE RURAL GROUNDS.

A Beautiful Azalea.—Very few flowering shrubs so combine richness of color with delicacy of outline when in bloom as Azalea amœna. Like some other members of the genus its habit is rather flat and rigid. The small, dark green foliage does not entirely conceal the stiff outline during growth, but in May the whole plant is smothered in a cloud of rosy purple bloom. When seen close at hand the magenta tint is not always pleasing, but at a little distance, when lighted by the sun, the effect is incomparably brilliant and pleasing. The innumerable flowers, often with double corollas, lose their individuality and give a lace-like effect that is quite unique in this class of plants. Azalea amœna is not entirely hardy north of New York, but can be grown successfully with moderate Winter protection to the Canada line. It should be planted in a sheltered position whenever possible, but there are fine specimens in this vicinity growing on rather exposed hillsides. The illustration on first page, Fig. 140, well represents a flowering branch, but can only give a faint idea of its extreme freedom of bloom. The picture was furnished by Bobbink & Atkins, Rutherford, N. J., who can supply this desirable Azalea as well as many other species. Azalea amœna is a native of North China and Japan, and is therefore at home in temperate climates, especially in hilly and well-forested districts. There are several native species of Azalea well worth transferring to our gardens. The beautiful flame-colored A. calendulacea from the Blue Ridge Mountains is scarcely excelled by any foreign hybrid. A. arborescens and A. Vaseyi, the former ranging along the summits of the Alleghenies and the latter nearly restricted to North Carolina, have large and handsome white or rose-colored blooms. Even the common eastern Azaleas, the "Spring honeysuckles" of every forest glade, A. viscosa and A. nudiflora, make desirable additions to a shaded garden. The large-flowered and beautifully colored Ghent Azaleas so abundantly forced for Easter blooms by florists are hybrids between various East Indian, Chinese and American species. Very few are hardy, even with the best protection, but they may be grown outside in moist soil during Summer, and wintered in a cellar or brought into bloom in the window garden. Some varieties may be forced repeatedly if given good care in the intervals, but the bloom is not likely to be as good as at first. Azalea amœna is regarded by some high botanical authorities as a variety of A. Indica and not as a distinct species. Most of the Azaleas were formerly classed with the genus Rhododendron, which is now confined to the large growing Rose bays.

Soil As a Commodity.—In most thickly populated districts good soil and leaf mold are in limited demand for potting plants, making up small flower beds and occasionally grading a lawn. When quoted by dealers in horticultural supplies the price is about $2 a barrel. Most florists furnish potting soil to their customers at very moderate prices, considering the trouble of getting up a well-balanced compost. In suburban resorts, where wealthy persons build costly Summer homes and improve extensive pleasure grounds, the demand for large quantities of rich top soil becomes quite imperative. The six-mile ridge of rolling upland between the present Rural Grounds and the ocean affords many desirable building sites on account of the great variety of water views obtainable, and has been in constant progress of improvement for the last 20 years. The soil near the sea is naturally so thin and poor that it will not sustain lawn grasses, while it rapidly improves inland. As the first improvements began near the beach much top soil was required to make a fertile surface, and farmers two or three miles back found they could get an average of 50 cents a yard for their soil with the profits for hauling usually added. Whole fields were stripped, the amount received in some cases reaching nearly $1,000 per acre. It looked as though these farms were ruined, and for practical agricultural purposes this probably was true, but with the advance of improvement inland the denuded fields came into market for building purposes, and were frequently sold at a still higher figure. It is not often that a piece of land can be bought at a high price, the surface skinned off and sold for more than the land cost, and the land itself later on sold at an advance over the purchase price, yet such has been the case in this locality. The marketing of sod for covering terraces and slopes as well as small inclosures, is a recognized industry in all suburban places, and has been considerably developed in this vicinity in connection with the trade in soil. Good firm natural sod is worth from one to 1½ cent a square foot, as it grows, and costs about three cents when laid in place. As a rule only a fraction of any given plot will produce good sod, but on some of the moist, rich fields many thousands of feet have been cut without seriously injuring the land. In hollows, where the soil is deep, successive crops have been taken without much deterioration. There is little good surface soil near Lakewood, situated just on the edge of the pine-barren district, and top soil is brought in by rail in large quantities for the very extensive improvements always going on. The business is locally in the hands of contractors, and the farmers have little to do with it except to sell their land when a sufficient price is offered. The stripping of a good meadow of its accumulated riches is no part of legitimate agriculture, and can only be profitable under such unusual conditions, but after all it is only restoring to the impoverished uplands the fertility they have been despoiled of by the storms of centuries.

Trifoliate Orange is Hardy Here.—Each day of the advancing season impresses one more strongly with the serious damage evergreen plants have suffered. The line of demarcation between the living and dying portions is constantly becoming more evident. Not for the past 20 years has so great loss been caused by climatic conditions. Deciduous plants came through the season very well, not being called on to transpire much moisture during the cold winds of February, when the roots were locked in frost. The plantings of the hardy or Trifoliate orange were little affected. As the trees grow older they gain in sturdiness, scarcely a twig being lost. They are really ornamental in Winter, the dark green of the bark rendering them quite conspicuous against a snowy background. If it were not for the slow growth there is little doubt the Trifoliate orange would become the most formidable and lasting of hedge plants in this latitude. The growth is thick and compact, and the long unyielding thorns defend it from any aggression by man or beast. Local trees have now reached eight or nine feet high, and have bloomed and fruited for several years past. They can easily be kept to a convenient height, and the tendency of all the winterkilling that has ever taken place here is simply to prune the plant by checked late and poorly-ripened shoots. A well-known nurseryman had such faith in the hedge possibilities of the hardy orange several years ago that he grew many thousands of seedlings, but he never could work up sufficient confidence in its hardiness to effect any but trivial sales, and in due course of time this interesting plantation was destroyed. It is not too much to say that scarcely anything grown in the nursery of equal age was less affected by frost than these unprotected little orange trees. It is, of course, understood that the fruit of the hardy orange is not edible, and of value only for the seeds when they are wanted. The plant is not catalogued now to the same extent as five or six years ago, but may still be obtained from some dealers at 15 to 25 cents apiece. The seeds are offered at 20 cents an ounce. They grow quite readily. Few plants have been encumbered with so many botanical synonyms, it having been described under four generic names, but the present designation of Citrus trifoliata is likely to stick.

A Potato Bug
is getting to be a hard bug to kill. So many poisons have been tried on him, he has become pretty nearly "poison-proof," but Bowker's
"BOXAL" WILL KILL HIM
and at the same time prevent blight of vines and rot of tubers, thus serving three purposes. We have many testimonials showing the truth of this in our catalogue of Insecticides which also contains a hand book of injurious insects and plant diseases, and how to fight them. 40 pages, fully illustrated. Ask for catalogue No. 21. Write to-day.
Bowker Chemical Co.
43 Chatham St., Boston

SAN JOSE SCALE.
And other Insects can be Controlled by Using
Good's Caustic Potash Whale-Oil Tobacco Soap No. 6.
Kegs, 50 lbs. ea., 5½c lb. | ½ Bbl., about 275 lbs., 4c lb
Kegs, 100 lbs. ea., 5c. lb. | Bbls., about 425 lbs., 3¾c lb
Kegs, 170 lbs. ea., 4½c. lb.
Large quantities Special Rates. Send for Circulars.
JAMES GOOD, 937 N. Front St., Philadelphia, Pa.

PARAGRENE
is better, cheaper and bulkier than PARIS GREEN.
"Have used Paragrene on my farm for potato bugs. It was perfectly satisfactory. L. H. BAILEY, Prof. of Horticulture, Cornell University." Write for sample. FRED. L. LAVANBURG, New York

SPRAY
Bugs, lice, scale, blight, black knot, yellows, fungus, etc., are all killed by spraying with
EMPIRE KING and GARFIELD KNAPSACK
Sprayers. Mix thoroughly and make fine spray. No scorching. No rubber or leather valves—something better. Brush keeps strainer free. Book on Spraying and agents' terms free.
FIELD FORCE PUMP COMPANY,
2 Market St. Lockport, N. Y.

SLUG SHOT KILLS CURRANT WORMS, Etc.
Used successfully 21 years. Sold by Seed Dealers. For pamphlet on bugs and blights, address
B. HAMMOND, Fishkill Landing, N. Y.

$5.00 Compressed Air Sprayer for $3.75
It is admitted by all classes of fruit growers and farmers that my 5 gallon compressed air sprayer is the most durable made. This reduction is made for a limited time only. Take advantage of the liberal offer—it may be your last opportunity to get the sprayer at the reduced price. $3.75 for galvanized steel, $5.00 for copper. Will throw a good stream 25 to 30 feet. Good pressure 20 to 30 minutes. The tallest fruit tree can be sprayed. Order to-day Salary to reliable men. Address
MARTIN WAHL Rochester N. Y.

Hope Farm Notes

STILL COLD.—I have heard of Winter lingering in the lap of May, but this year May had such a cold that she could hardly get up and dress. It is true that the plums burst into bloom about May 1, with the cherries a few days later, but the trees looked like men who put on straw hats about three weeks too early. The apples are far behind their usual season. . . . . The rains have kept up, with cold, windy days between them. Our hard, cold soil has had no chance to dry or warm. We are planting potatoes slowly, but I don't know that it is wise to put the seed into this cold soil. Corn planting will be very late this year. . . . . There is no use grieving over the weather. Both the just and the unjust are getting their full share of it. Far better consider the crops that are being helped by it. Our little peach trees are thriving. This wet soil just suits them. They are shaking out their leaves in great shape. The seedling cherry trees that were planted along the stone walls enjoy this weather. So do the rye, grass and Crimson clover. The cabbage plants are thirsty friends, and so are the newly-set strawberries. There are two sides to this weather question, and the live farmers will try to have something in the ground that will rejoice at anything the weather clerk sorts out.

FARM NOTES.—I love to see the little plants of Red clover pricking up among the oats. These green babies will work for the farmer when they grow up, and leave the soil better than they found it. Our seeding is coming up finely. The damp soil has helped the clover. . . . . The oats are starting well. Of course we treated the seed with formalin. I am sure that this helps the plant from the very start. When the smut germs are in the seed they may begin their work at once as the sprout starts, and the little plant never has a fair showing. I have seen oats which paled and limped along from the start, never making a decent crop. This was largely due, I think, to smutty seed. The plants never had a fair show any more than a calf born with the germs of tuberculosis in its body can hope to grow into a first-class cow. I am told that formalin is also used to prevent Onion smut. . . . . The most valuable thing thus far about our experiment with the Clark grass seeding method is the fact that we can see our mistakes. They are certainly written in green ink. Where we did the work just right the field looks like a thick lawn. What was "right?" Why, the stones were all picked up, the ground nicely graded and the seed evenly distributed. There are brown streaks and patches in our fields, some of which stand as monuments to our own errors. In some places the stones were not picked up clean. The soil was all carefully fitted, but part of it was not graded. On every little lump and ridge I notice the brown soil showing like the bald spots on a man's head. We put the seed on carefully by hand, but with the wind blowing it was scattered more or less. I now see why Mr. Clark wants to work the field several times with his light harrow after seeding. This mixes it up and makes it even. Where we did our full duty the grass is thick and strong—good evidence that the Clark method is O. K.

THOROUGH JOBS.—But is it possible for the every-day farmer to go through all these motions and take such pains with his grass? He may have only one team, and there will be a dozen jobs pressing at once. We would not ask that question if we could have faith, and know that we can make one acre do the work of two if we would only take care of it. Most of us are in the habit of spreading our labor over a certain area. Work and weather catch us at the wrong time, so that we never can say that the crop was perfectly cared for. How many have actually tried the plan of cutting down the area and working fewer acres better? We shall try that this year with our potatoes. We lost a share of the crop last year because we could not get over it thoroughly. This year we shall have but little more than half the acreage, but that will mean nearly twice as much attention to bug, blight and weed. My conviction is that it will pay me better to seed down two acres each year on the Clark method than it would to scratch over five acres and half seed it—as is usually done. As a fellow grows heavy and feels the rheumatism in his joints he may be excused for thinking twice before he tackles useless jobs. If I could be 20 again, and carry my experience back with me, I would never make a mere smatterer—running and fooling after a lot of different things, but I would master one of the common things of life or come as near to it as I could. Who in the world cares to listen to some 'prentice or amateur trying to play "Listen to the Mocking Bird" or "Old Black Joe" on violin or piano? Nobody but his father or mother; but let some master of the instrument start these simple old tunes and we will gladly listen all night. Why? Because these players pour the soul right out through their fingers. In those few minutes they give us a taste of the mastery which they have won through years of fight and self-denial! It is about so with Mr. Clark and others who have fought for mastery over some crop or farm method. They show us the way to get out of 'prentice work and master the forces of nature.

FAKE PROMISES.—I find fault with some of these writers and speakers because they paint up one side of the thing in glowing colors and bury the other end in the ground. Their excuse is that if they did not tell a "big story" the farmer never would start. In some cases he would be better off if he didn't. As an illustration of what I mean I will say that we are starting in the milk business. We sell to neighbors who take at present six quarts per day, and want eight or 10 quarts later. We can get six and eight cents per quart. Now I might say this about our milk trade: "We have no trouble in selling all the milk we produce at six and eight cents per quart. This milk is so good that a gallon of it represents a pound of butter. When farmers say that they can get only two cents a quart, we judge from our experience that it must be because they have poor milk or else they do not put brains into farming!"

Now, I read many articles that are just about as sensible and helpful as that would be. It is true that we sell our surplus readily but it is only a small side issue with us. How foolish to apply it in the case of a farmer who makes milk for a living. We can sell a gallon of milk for 25 cents and buy a pound of butter with the money, but as I have put it above it appears that our milk contains 19 per cent fat! I submit that some of these folks who put up a wise bluff and keep all the shade out of the glowing pictures they draw have sometimes less of fact than I have in the above statement. "Brains into farming!" Why, our milk could not compete in the New York market with that produced on the back farms! We would most likely starve to death if we tried to make a living on those milk farms! Some of these fellows dress up our honest friends the hen, horse, hog or cow—not to mention apple and potato—so that they are truly wolves in sheep's clothing luring farmers on to throw away their hard-earned dollars.

STOCK NOTES.—The Hope Farm men, women and children think highly of their live stock, but we really can't tell any very big stories about them. Julia is still kicking out veal and milk. Ape and Pril—the two calves born in April—are milking her and separating a large per cent of veal. Now that our little milk trade has started we feel more like taking the kick out of Julia, for she will make a peck of bran per day change into the grain needed by all the horses! . . . . The little Berkshires are thriving. Here you have their weight records: March 19, 14 pounds; April 1, 31 pounds; April 8, 45 pounds; April 15, 60½ pounds; April 22, 78 pounds; April 29, 97 pounds. One little sow weighed 26 pounds on April 29. They are very satisfactory. Little Billy Berkshire has a bob tail, but his hams and shoulders make up for any tail defect. I am told that this loss of the tail in little pigs is quite a common thing. Speaking of weights a farmer in my own county sends me the following:

"Litter farrowed March 19, number of pigs when farrowed, five live and one dead; cross between Berkshire boar and grade Chester White sow of small size (about 200 pounds), pigs of even size. Weight on April 27, 39 days old, 120 pounds (best one 26 pounds); average 24 pounds. I will give you the weight of this litter next Saturday again; it was farrowed the same day as yours, and it is a fine bunch of pigs of even size." C. J.

Our hens laid 674 eggs in April. Taking out sitters and loafers the flock averaged 45. In addition to shelling out these eggs the hens had dug and burrowed in the season's garden. Their yard has been plowed twice and will be plowed again. Then the hens are turned out of it into another yard and their old runs planted in onions, Lima beans and sweet corn. I have said many hard things about the dog. Some of them I will stand by as long as I live, and will invent words to make them stronger. I must admit, however, that there are dogs that are gentlemen. Shep, our Scotch collie, is a nobleman in fur. He, like old Major, Jersey and Peter will end his days on Hope Farm. The intelligence and loving character of this dog have astonished me. Many a day while wandering over the hills alone Shep has followed, snuggling up against me like a child whenever I stop for a moment's rest. If every farm family could have a dog like Shep the world would be better off. That is strong language for a man who has insulted the dog as often as I have!

H. W. C.

What is Black Knot? Its Cure.

We often receive questions from readers who ask about the disease known as black knot. The following simple statement by Prof. C. O. Townsend, of the Maryland Experiment Station, seems to answer such questions fully:

Black knot is a fungous disease affecting both wild and cultivated varieties of plums and cherries. It is an American disease that has been known for more than 100 years, and so far as can be determined had its origin in the eastern part of the United States. For a long time the knots were supposed to be due to stings of insects, but careful examination has shown that they are due to a distinct and well-known fungus (Plowrightia morbosa). In appearance the knots are at first light brown in color, but gradually deepen with age until they become perfectly black. The first indication that a knot is forming is a slight swelling under the bark, the swelling increases until the bark splits and the brown surface of the knot appears. These abnormal growths may form on any part of the tree, i. e., either upon the branches or upon the trunk. The fungus that produces the black knot forms two sets of spores; one set known as Summer spores is produced early in the Spring, usually in May, the other set, called Winter spores, is formed in the late Fall or early Winter, usually in December. The Summer spores are capable of germinating just as soon as conditions are favorable; hence, if they chance to lodge in a suitable place upon the tree they will form new knots. The Winter spores do not germinate immediately, but retain their vitality until the warm, moist days of Spring come, when they germinate and produce new knots similar to those produced by Summer spores. The fact that this fungus forms two sets of spores accounts for its rapid spread and for its very destructive nature. The spores seem to be able to cling to almost any part of the tree, especially where the bark is rough, hence we find the knots forming most frequently in the crotches of the branches. The fungi produced from these spores are able to penetrate the bark at all points, even on the trunks. After the fungus has penetrated the bark and produced a knot it grows between the bark and the wood for several inches beyond the visible knot, so that the removal of the knot does not remove all of the fungus.

With these facts in mind the remedy for the trouble readily suggests itself. In the first place the knots themselves should be cut off and burned. If they are growing upon twigs or branches, the affected parts should be cut off several inches below the knots, in order to remove all of the knot-producing fungus. If the knots are growing upon the trunk or upon large limbs they should be cut off, and the bark for several inches in all directions should be removed and burned with the knots, and the surface should be washed with a fungicide (iron sulphate, one pound in 20 gallons of water). If the trees are very seriously infested they should be cut down and burned completely and promptly. Having removed and burned all the knots the next step consists in spraying the trees thoroughly with some fungicide in order to destroy any spores that may be lodging upon the branches. Probably the most satisfactory fungicide is Bordeaux Mixture, which should be applied just as soon as the trees can be freed from knots. The spraying should not be confined to the diseased trees, but all plum and cherry trees in the same vicinity should be sprayed in order to destroy any spores that may be lodging upon them. This treatment should be repeated several times through April, May and June. In spraying after the foliage appears it must be remembered that full strength Bordeaux Mixture is liable to injure the leaves of Japan plums, hence a mixture containing a small amount of bluestone (two pounds in 40 gallons of water) and a large excess of lime should be used at that time. The earlier the knots can be cut out in the Winter the better, and they should by no means be left until the foliage appears, as they are then obscured, and sometimes hard to find, especially when they are small.

For the land's sake, use Bowker's Fertilizers. They enrich the earth.—*Adv.*

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

Choice Vegetables always bring high prices. To raise them successfully, a fertilizer containing at least 8% Potash should be used.

SUBSCRIPTION: ONE DOLLAR A YEAR.

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs.

"A SQUARE DEAL."

We believe that every advertisement in this paper is backed by a responsible person. But to make doubly sure we will make good any loss to paid subscribers sustained by trusting any deliberate swindler advertising in our columns, and any such swindler will be publicly exposed. W protect subscribers against rogues, but we do not guarantee to adjust trifling differences between subscribers and honest, responsible advertisers. Neither will we be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent us within one month of the time of the transaction, and you must have mentioned THE RURAL NEW-YORKER when writing the advertiser.

Name and address of sender, and what the remittance is for, should appear in every letter.
Remittances may be made in money order, express order, personal check or bank draft.
THE RURAL NEW-YORKER,
409 Pearl Street, New York.

SATURDAY, MAY 18, 1901.

To January 1, 1902, for 50 Cents.

During the last two years we have received several thousand letters thanking us for the new rose, Ruby Queen, most of them saying at the same time that the writers are always glad to do a good turn for THE R. N.-Y. We are going to give these good friends a chance now to interest their neighbors in the paper. We have some roses yet left. Get two of your neighbors to give you 50 cents each, send us the dollar and their names and addresses. We will send them the paper the remainder of this year, and each a rose by return mail. For your part we will send you postpaid Mr. Stringfellow's New Horticulture, which is advertised in another column, for 50 cents. We hope to hear from several thousands of our friends on this proposition. Do not put it off. See what you can do at once.

*

OUR advices indicate that the strawberry crop in the South is both short and late. If it were short and not late the prospects for the northern crop would be better. Prices would be likely to remain high right through the season. The crop is late, however, and a few days or weeks of hot sunshine may quicken the growth in northern sections so as to bring on a glut after all.

*

THE oleo men admit that if the Grout bill had ever come before the Senate it would have passed. A majority of the Senators favored it. The oleo men defeated the bill by what they call "parliamentary advantage." It reached the Senate late in the session at a time when a good many important measures were crowding. By playing off one interest against another the oleo people were able to hold the bill up. The remedy is to bring it before the next Congress at once, and push it harder than ever. Let us try to get the stumps out of the road beforehand. One tough-rooted stump is J. W. Wadsworth, chairman of the agricultural committee. Pull him out by all means.

*

IN a wholesale liquor store in this city is an odd-looking clock. The works are in a beer barrel, which is placed on a high shelf. One end of the cask is painted to make the dial around which the hands turn. In whatever form he appears, time has lessons for all, even though they refuse to hear or heed. Intoxicating drinks not only rob a man of his money and brains, but of his time also. Surprising figures might be shown if some one could keep a correct account of the time spent by the patrons of a busy saloon in one week in drinking and getting over it. The old clock in the beer keg says: "You may bottle me up, but still I point out to you the swiftly-flying minutes, which multiply to hours and days and years and lifetimes." Time is a slippery customer. Chains will not hold him, and he will duplicate no wasted moment.

*

THE recent pigeon-shooting tournament at Interstate Park, N. Y., during which 20,000 birds were butchered to gratify cruel ambitions, has been followed by such a clamor of public execration that a bill to outlaw the inhuman sport has been forced through the New York Legislature, and only awaits at this writing the Governor's signature to become law. Great opposition was manifested to this salutary bill, which places pigeon shooting on a legal par with prize fighting and some other brutal pastimes. It is said that the most formidable opposition came from powder manufacturing companies, which find their business interests imperiled, but it is to be hoped that their influence will not finally prevail. While such exhibitions are always degrading to participants and spectators, if the pigeons or other live birds were all killed outright it would not be so revolting, but many of the helpless victims flutter out of reach after receiving ghastly wounds, and slowly perish in agony. The necessary skill can be shown in shooting at the various ingenious mechanical substitutes for living birds now on the markets. Such an exhibition of public conscience and sympathy as preceded the passage of the bill is most gratifying in view of the flood of "strenuous" talk let loose on the community during the late political campaign by persons who think it the acme of manliness to kill or maim some helpless creature under the guise of sport. While this law, if approved by the Governor, will stop the cruel pastime in New York it is still free to go on in neighboring States like New Jersey. It is to be hoped that no R. N.-Y. reader will countenance live-bird shooting in any locality, nor be instrumental in supplying birds for such purposes.

*

So great has been the demand for rural free mail delivery that nearly all of the $3,500,000 appropriation has been provided for. Unless Congress votes more money at its next session many new applications for routes cannot be considered. There are now about 3,000 routes in operation, and 500 more have been ordered by July 1. There has been nothing in recent years quite like the growth of this demand for better mail service. Most of us remember how gingerly the Government handled it at first. The authorities seemed to be afraid that farmers would not appreciate the business and social advantages of this service. So they went about it in a sort of half-hearted way. They ought to have known better than to lose faith in the good sense and intelligence of the American farmer. Such a demand for an increase of the service came rolling in that no one now thinks of giving it up. The only question is—how rapidly can it be extended? The American farmer will obtain his share of benefits when he wakes up to the fact that public rights result from demands, not from begging!

*

THE Kiowa and Comanche Indian reservations are soon to be opened up for settlement. Such "openings" in the past have meant a mad rush and gamble in which the actual home-seekers usually had the worst of it. This land is supposed to belong to all the people—why should a few be permitted to grab and gobble it? There are 1,400 quarter sections of this land, and it belongs to eastern people as well as to those who live west. One of our readers in New England suggests the following plan:

> It seems as though we, who live so far from the fine lands of the West, and most of us in New England, for instance, farm rather poor land, ought to have as good a chance, if only by lot, as those fellows in the West who make land speculation a business. There is little good land left. Is there any reason why all could not have share alike? Why could not lots be drawn for all of it, and men in Oregon, or Florida, or Vermont, all stand on the same footing? I know it is objected that such a distribution would be contrary to the law against lottery, but such a law was aimed at concerns which have for their object the fleecing of the many for their own benefit, and incidentally the demoralizing of a few by the expectation of big or little prizes. Where nothing is paid by the citizen, and no demoralizing influences are present, how can the law be infringed any more than drawing a jury by lot? It would be absolutely fair for all, and under the supervision of the Government, these lands would be allotted to citizens, who might apply, from all over the country.

*

WE know a man who a few days ago sold his seat in the New York Stock Exchange for $65,000. About 20 years ago he bought this seat for $1,000! What can there be about such a thing that can command this value? This "Exchange" is limited in membership. Only those who are members may go upon the floor during business hours and buy or sell stocks. As the vast proportion of sales or transfers are made at the Exchange, and go through a system of recording and transfer, it is easy to see what a tremendous advantage such membership is. Just now a member can probably make at least $1,000 per month by simply becoming a partner in a firm of brokers, thus giving them a chance to handle stocks on commission. We speak of these figures to show the immense advantage conferred by this great business organization. The whole system is more or less of a gamble, though it is fair to say that were there no such "Exchange" the frauds and bogus concerns would have a better chance to fleece the public. So far as the farmers are concerned all this stock gambling is opposed to their interests—for they pay every dollar of the cost in the end. No one can object to actual sales or transfers of stocks or of grain or produce. There would be little gambling about such transactions. The actual stocks or products are not sold at all in many of the transactions, which are really bets on the *price* of the stocks. As the prices are forced up or down the investors win or lose. The man who gambles in a game of cards has at least a chance to play his own hand. The stock gamblers know nothing about the workings of the game. We believe that National legislation is needed to prevent dealings in "options" or gambling in prices. The Washburn bill, which was aimed at this abuse, was killed in the United States Senate several years ago. It should be revived!

*

THE Hope Farm man has been pleasantly criticised because he is hunting for something that will provide a profitable Winter job for a large family. One trouble on many farms is the fact that the labor which produces actual money is crowded into a few months. The rest of the year is occupied with chores or odd jobs which produce little cash. We all understand the evils of such a system of incomes. Near towns and cities one result is that cold weather freezes the hired man out of his job, and sends him to town—too often to join the ranks of the idle or half employed. The effect on the farmer's own family is often bad. They are overworked during the busy season and do not always use the Winter to the best advantage. It is usually hardest for the women, as they have few of the things they need when the farm income is small. We feel sure that personally most large country families would be better off for some attractive Winter job that would pay fair wages. The farmer would be able to keep a good man through the entire year. His own family would be happier and more hopeful, for attractive and profitable labor is the great sweetener of human life. Discontent is bred by heavy, underpaid drudgery or unprofitable idleness. In a public way, too, a good solution of the farm Winter-job question would benefit the country. It would help spread industry and population, taking them away from the crowded towns where they are as great an evil as an overcharge of blood in certain organs of the human body. There are good arguments in favor of the farm Winter job and but little to be said against it.

*

BREVITIES.

Just take your learned scientist,
  Put in his hand a hoe,
And lead him out into the field
  And point him to his row.
What living, think you, he would dig
  Out of the richest dirt?
His stomach would show lack of food,
  His back would lack a shirt.
You take the farmer from his plow
  And put within his hand
The test tube and the microscope
  Where, think you, *he* would land?
What living, think you, he could earn
  In such an awkward place?
What truths would his untrained eyes find,
  In Nature's heart and face?
Why should we blame the scientist
  Because he finds the hoe
An awkward tool and only knows
  The *why* of how things grow?
And why despise the man of soil?
  To this all must agree
Without his work your science would
  Remain a theory.

WHAT is the outlook for hay and fruit?

THOSE who bridle sin provide a mount for the evil one.

THE tomato is fast growing away from vegetable into fruit.

NOW, gentlemen, what will keep rabbits away from young trees?

A MOLE becomes nearest to being a mountain when on a human nose.

HE who will not master common things, must take his place among the underlings.

TO put the "kick" inside your hatching eggs—induce your hens to scratch and use their legs.

WHEN time lays bare the motive how ashamed some of us will be—who have been judging the deed alone.

SOME people spend life trying to reach what they would like to be with little thought of what they should be.

YES, some of those who are trying to boom the Angora goat will surely go among the goats at the last sorting.

ONE of P. D. Armour's rules of business was: "Don't talk too much." Let farmers' institute workers know how dangerous their position from becoming talking machines.

A REMARKABLE old horse has just been turned out to grass in Newark, N. J. He has been used for producing antitoxin for diphtheria. He cost $15 originally and has produced $9,000 worth of the antitoxin.

DR. J. J. BLACK says that the boy's green-apple stomach ache is as likely to result from "the pathogenic germs that go down with the apple" as from the fruit itself. It's lucky our ancestors did not have a knowledge of germs added to their other troubles.

A READER gives the following as a "sure cure" for scours in calves: Boil corncobs in water for an hour—give the liquor warm. Medical men find little in corncobs that would have any such effect. Probably simple boiled or sterilized water alone would help.

WE have a dozen questions about to how handle seed corn so that the crows will not pull it. Our way is to tar the corn. We use the ordinary thick tar. Add a little water so that the corn will become fully smeared. Then dry by sifting ashes over it. The crows in our part of the country will let such corn severely alone.

Events of the Week

DOMESTIC.—President and Mrs. McKinley, members of the Cabinet and their wives and a few guests departed from Washington April 29 on the journey across the country, during which they will visit 25 States, travel more than 10,000 miles and be absent more than a month. . . . . The Pan-American Exposition was opened to the public May 1. Formal opening and dedicatory ceremonies will be held May 20. . . . . Van B. Triplet, inventor of the gold brick, who is said to have swindled people out of a million dollars by different kinds of confidence games, died May 2 at West Baden, Ind., in poverty. Money was raised by his friends to give him decent burial. Triplet, who was also known as John V. Tripp and "Old Tripp," was well known by the police in Chicago. He was born in Virginia 60 years ago and came of good family. He began a life of crime when he was young, and for more than 40 years had been pitted against the police. . . . . A destructive conflagration occurred at Jacksonville, Fla., May 3. The fire broke out about noon. A large section of the business and residence portion of the city was destroyed, and the losses are estimated at from $8,000,000 to $10,000,000. Six lives were reported lost, and 10,000 persons were homeless. . . . . Thousands of persons are pouring into Southwestern Oklahoma and camping in and about the Kiowa, Comanche and Apache and Wichita Indian Reservations for the opening, scheduled for some time in August. . . . . May 3, 13 barges and a tug were sunk in a collision at Evansville, Ind., entailing a loss of $45,000. . . . . A dynamite explosion May 3 at Oates Camp, on the Asheville and Nashville Railroad, in Tennessee, resulted in the death of two men and severe injury to several. . . . Seven persons were burned to death, three fatally injured, and several slightly burned in a fire at South Chicago, Ill., May 5. The fire engines were blocked by a freight train, whose crew refused to move from a crossing, and the firemen could not reach the burning building until too late. . . . . Fire in a wool warehouse in Philadelphia May 6 caused a loss of $375,000. . . . . An epidemic of smallpox has broken out at Gloucester City, N. J.; 15 cases were reported May 6. . . . . Four children, left alone in a farmhouse at Muskegon, Mich., May 3, set the house on fire and were burned to death. . . . . May 4 a fire in the Chicago stockyards destroyed a large butterine plant, the loss being $150,000. . . . . Two practical jokers at Davenport, Iowa, May 7, while pretending to hang a companion, were killed by a falling pulley and scantling. Their intended victim was slightly injured.

GENERAL FOREIGN NEWS.—Distressing accounts are arriving at St. Petersburg, Russia, of the situation of the villagers throughout Bessarabia, especially in the Soroki district, caused by the famine arising from the failure of the last harvest. The peasants are living on husks of maize boiled in water. Half of them are suffering with typhus fever. They are clad in rags and have no furniture or other household necessities. Horses and sheep have decreased from 50 to 60 per cent, owing to lack of forage. In some villages horses are sold at a ruble each. Elsewhere 70 per cent of the farmers have lost all their horses. . . . . Secretary Jackson, of the United States Embassy at Berlin, informed the State Department that the German authorities at Hamburg would not permit the shipment in bond through Germany of sausage intended for the Austrian market. The matter was brought to the attention of the proper officials, and it was found that the action of the German authorities was due to a misunderstanding. The customs authorities have been instructed that no objection exists to the shipment of canned meats and sausage through Germany in bond. . . . . C. J. Van Houten, who died recently in Algiers, rightfully deserved the title of prince of cocoa manufacturers. The house of Van Houten began business in Weesp, Holland, in 1817, having been launched on its great career by the father of the late proprietor. The factory, which covers an area of eighty-five acres, employs 3,500 people.

FARM AND GARDEN.—In the annual report of C. F. Saylor, special agent in charge of the beet sugar investigation of the Department of Agriculture, an active tendency toward the institution of new beet sugar enterprises is shown. Next Autumn, he says, Michigan will have three new factories and Ohio, Indiana, New York, Colorado, Utah, South and North Dakota and Illinois will install new factory enterprises, making 13 throughout the United States now in contemplation. A conservative estimate, he says, is that there will be 42 beet sugar factories in operation by the end of this year. He adds: "Even in the incipiency of the industry these factories have shown good profits. They have maintained themselves without any apparent contest with the sugar trust. The sections of the country that seem most adaptable to the industry are where conditions call for new resources, as in Michigan, where there has been a phenomenal increase in the last three years, largely due to the waning of the lumbering industry of that region."

The Summer meeting of the Missouri State Horticultural Society will be held at New Haven, Mo., June 4-6, 1901. Spraying for insects and fungous diseases will be an important feature of the discussion.

The Michigan State Fair will be held at Pontiac, Oakland Co., September 23-27; secretary, I. H. Butterfield, Agricultural College, Mich.

The Secretary of Agriculture has ordered a thorough investigation of all matters pertaining to the distribution of Government free seeds by the contractor during the present year, and has delegated Professor B. T. Galloway to do the work of investigating. Professor Galloway is "required to make full and complete report, so that it may be in evidence when final settlement is made with the contractor." An announcement is also made by Secretary Wilson, to the effect that after July 1, 1901, "all matters pertaining to the Congressional distribution of seed, including the control of the employees of the Seed Division," shall be in charge of Dr. Galloway.

Tobacco men in Wisconsin say that there will be an increase of acreage this year. Considerable interest now centers in the production of plants, which is always taken as an indication of what the farmers will do during the season. The plants are reported as being backward, owing to the dry weather, but there are indications that millions will be needed to supply the increased demand. Considerable effort has been put forth to produce an early variety of seed, and a large quantity is now sown in the plant beds. Deliveries of the crop of 1900 are very large, and the hundreds of warehouses are well stocked with tobacco waiting to be sorted and packed. Many buyers are in the field, and shipments are reaching in some places 1,000 cases a week. Many of the warehouses are holding crops back as far as 1896, and some of the farmers are still holding back crops.

GENERAL CROP PROSPECTS.

Peanut buyers in Virginia are rapidly absorbing all of the better grades, on some of which an advance has been made. The lower grades are plenty and hard to sell.

The wheat acreage in eastern Washington is greatly increased this year. It is said that in Whitman County 50,000 acres of land will produce its first crop of wheat this season. One farmer last year plowed up 1,000 acres of sage-brush land, which was thought to be about worthless, but the weather was favorable, and his experiment resulted in a yield of nearly 30 bushels per acre. This Spring many other owners of this sage land are following his example.

Parts of Georgia and Alabama have suffered severely from hail. In some sections it is thought that three-fourths of the young cotton has been destroyed. Damage was also done to corn and vegetables on the truck farms. The storm began a little before midnight, and on some of the hills the halistones remained on the ground until nine o'clock the next morning.

Last year's Kansas wheat crop lacked about 10,000,000 bushels of the figures estimated at the time of harvesting. This year indications are, if anything, more favorable than last, and a 100,000,000-bushel yield is expected. A Kansas mathematician has been doing some figuring,

THE BOOM IN WALL STREET.

THE AMERICAN FARMER: "After all, the prosperity of these money-makers is based upon my hard work!"—CHICAGO RECORD-HERALD.

and finds that the wheat crop of that State in the last three years has brought in enough money to topdress the whole State with dollar bills two deep. A newspaper reports that Kansas has sent out a call for 15,000 young men to work in harvest at $2 per day. No one should "bank" very much on this report, and certainly should not go until he verifies it and learns further particulars. The chances are that a big supply of incompetent so-called farm hands will float in. Kansas folks are hustlers, particularly at harvest time, and no one need go unless he is willing to "pitch in" and earn his $2.

Reports from Southern California place the yield of prunes at about one-eighth, and apricots and peaches one-fourth that of last year. It is said that the prunes are of uncommonly large size and good quality.

The Southern Strawberry Crop.

The cold, wet weather made the crop late, but more favorable now, and probably a very good crop will mature. S. P. S.

Bensalem, N. C.

The prospect for the strawberry crop is all that could be expected. The plants are looking fine now (May 7) in about full bloom, all except Gandy. The acreage is about the same as last year. Some growers have more, some less. Some who did not give their patches the best of care last year do not have a good set of plants, but most planters have plenty. The weather has been favorable. Raspberries, I think, will be short. S. J. D.

Greensboro, Md.

The strawberry crop is poor; in the dry season of 1900 the plants made no growth, and it is conceded by most growers that half crop, compared with last year, is as much as can be expected. The crop will be two weeks later in ripening than last year, owing to weather being so cold up to the beginning of this month. The season is fine now for all crops—plenty of rain, and for a few days past the weather has been quite warm, temperature up to 85 degrees at noon. Wheat and grass are very fine; apples, peaches, pears, cherries, plums, etc., all show for a big crop. A. W.

Crozet, Va.

The berry crop will be very short in this section. Under the most favorable conditions from now, not over 75 per cent of a crop can be harvested. We are having exceedingly dry weather, with high temperature, and very brisk winds, and unless we have rain in a few days, a greater shortage will occur. This is the largest shipping point for berries in North Carolina, and conditions are said to be more favorable here than elsewhere in the berry district. We are about twelve days late.

Mt. Olive, N. C. J. O. L.

The California Prune Growers' Association.

The affairs of the California Prune Association have improved. The cut in price and extra efforts made resulted in sales sufficient to pay the debts of the Association, give a dividend of one cent a pound to growers, and leave a small surplus toward the next dividend. The cut has now been revoked, and it is said that an order for 8,000,000 pounds at the low rate was refused. This favorable turn of matters has caused a better feeling on the part of the growers, and it is likely that the Association will be continued. It is said that an effort will be made to get all the small prunes out of the market by making them up into preserves or jams, the object being to prevent speculators from buying them up at low figures to put on sale next Fall. This cut in price, although criticised, has been a good thing. If a tree or vine makes too much wood in a season, it must be pruned severely, and there is no reason why a heavy surplus of prunes should not be pruned also. Holding a large quantity of perishable food is a poor plan, particularly when a new crop is but a short distance away.

Southern Fruit Crop Notes.

The frost the latter part of last month seems to have done considerable damage to early fruits and vegetables in the trucking districts of the Carolinas, Virginia and the Peninsula. Many South Carolina cucumbers will have to be planted over. Strawberries also got a set-back. Indications for the North Carolina cantaloupe yield are said to be promising. The returns from the strawberry crop in Delaware for the past two or three years have been so unsatisfactory that some growers have plowed up their fields. It is thought that the Georgia peach crop has come through the cold snap without serious injury. Still, some authorities claim that the stems have been weakened by the cold and high winds, and that on this account a much larger proportion of the fruit than usual will fall. The curculio is active, and growers are spraying with Bordeaux as a preventive of the brown rot, which did damage last year. Some claim that the addition of two ounces of Paris-green to 50 gallons of Bordeaux will help in disposing of the curculio. It is generally conceded, however, that sprays have but little effect on this hard-shelled customer, the only effective treatment being jarring the trees.

Government Weekly Report.

In the South Atlantic and Gulf States rain is needed, particularly in the parts of the cotton belt that have been replanted. Moisture and temperature conditions for the Northern and Central States are favorable, and plentiful rains have fallen in parts of the Rocky Mountain plateau. On the Pacific coast cool weather prevails. Corn planting in the valleys of the Central South is rapidly going on. In parts of the extreme South, where the corn is already up, the stand is uneven, owing to unfavorable weather. The Winter wheat outlook is generally favorable except in Michigan, where the stand is so uneven that some has been plowed under, and in parts of Texas and Oklahoma, where insect damage is reported. Winter wheat on the Pacific coast looks unusually fine. Early-sown Spring wheat promises well except in Minnesota. Drought and insects are injuring oats in Arkansas, Oklahoma, Texas, and parts of Illinois. Fruit trees in the North, except late apples, are generally in bloom. In Ohio and West Virginia apple trees have blossomed unusually full. In the tobacco districts the outlook is favorable. Small fruits in the Central States in healthy condition. In the Atlantic States strawberries are backward.

FIGHTING PEA LOUSE.—Last year the Pea louse made its first appearance in this locality, destroying about 50 per cent of the crop. Early peas, however, were not at all affected. Gregory's Surprise and Nott's Excelsior furnished last picking July 4. Then the lice came in swarms. Abundance and Juno, 50 to 60 per cent destroyed; Stratagem, total loss; Champion of England, 50 per cent. This experience would seem to indicate that we would better confine our planting to the early sorts, yet if I remember rightly one of your Connecticut correspondents wrote that his early peas suffered the most. The outlook is decidedly dubious. However, we purpose to plant about as usual, and if the louse puts in an appearance brush him off and bury him, as that seems to be the only effectual remedy yet discovered.

Jewett City, Conn. H. H. B.

THE MILK SITUATION.—The cows in this section are in fair condition, although some of the farmers have had to buy hay. Most of them now feed heavily of grain, so as to have hay to carry them through. Pasture is short, though we have had plenty of rain, but the drought of the last two years hurt the fields, so feed will be short all Summer, and the milk flow will be below the average. The farmers reduced their herds last Fall, so there is little sale of cows this Spring. Cows bring from $25 to $35, only a few being sold at the highest figure. Most of the farmers try to raise enough calves to keep their dairies good. Most of the cows through this section are crossed with Jersey and Durham; a few purebred Jersey. This seems to be about the general-purpose cow. There is hardly a dairy that will not test four per cent butter fat, and some will test over five per cent. There are no cows for sale that I know. The farmers are getting sick of the milk station, and are making butter and taking to factories. They are talking of putting up a coöperative creamery next Fall. If the farmers would sell their scrub cows and keep fewer cows and better ones, and buy less feed, they would have more money at the end of the year. We have a good many cows that are only boarders and do not pay their keeping. Sort them out and sell them; they are dear at any price.

Great Bend, Pa. W. G. H.

Woman and Home

From Day to Day.

CLEANING TIME.

Beneath the burnished chandelier
The weary housewife stands,
With scrubbing brushes, dampened cloths
And such things in her hands,
And in a rasping tone she gives
The hired girl commands.

A rag is wound around her head
To keep her hair in place;
She has the bed clothes wildly piled
Upon the dressing-case—
Her nose is skinned and there are broad
Brown streaks across her face.

From room to room she makes her way,
And madly rips and tears;
Her husband helps throughout the day
To run the world's affairs,
And sadly wanders home at night
To sleep upon the stairs.

—Chicago Record-Herald.

*

HATS trimmed with straw braid and straw buttons are characteristic features of Spring millinery. Sometimes the straw braid is used to combine with silk muslin. Long, rather flat bows of straw braid are apparently fastened down with straw buttons the size of a quarter. It is a style, however, that easily becomes clumsy.

*

OLD-fashioned crochet buttons are having a fashionable revival; in addition to forming rows of trimming and bunches of pendants, they are used on heavy lace, like the familiar rings. Those who have a supply of these buttons laid away, relics of out-of-date garments, may now bring them forth. Sometimes they are used as pendants to tip chenille ends. Rosettes of chenille with a few dangling ends are used as trimming, the chenille used being about half an inch in diameter, and costing 12 to 18 cents a yard. To tell the truth, we have always violently disliked chenille as a dress trimming; it suggests lamp mats and tidies, but there is no question of its style at present.

*

THE Atchison Globe tells of a man in that town who solemnly swore that one day was sufficient to give a thorough Spring cleaning to an eight-room house; he considered that women waste entirely too much time in pottering around. As the result of a wager with his wife, he completed the cleaning in the time specified, but history is cruelly silent as to how it was done. It is an undoubted fact, however, that the heavy labor of house-cleaning is properly men's work, and we know one country town where a capable colored man makes engagements for housecleaning months in advance. He descends on the premises with aids who work under his directions, and the thoroughness and celerity with which the work is done is a revelation.

*

ONE of the ocean steamship companies in New York decided some time ago to place the most modern rubber air mattresses in the best staterooms in two of its biggest ships. One of the great advantages of these mattresses is that they may be used as small rafts or life preservers should the emergency arise. The manner in which these mattresses collapsed was a puzzle to the stewards, who had to inflate dozens of them after each trip. It was finally discovered that they were stabbed to death by the women passengers, who used them for pincushions. The average hatpin will effectually destroy the ambition of any air cushion and apparently everything in the pin line had been stuck into these mattresses. The steamships now have a notice attached to the doors of the staterooms, requesting passengers to refrain from the practice. This is a case where one might die from a pin prick, since, in sudden disaster, the uninjured air mattress may buoy up a victim until rescued.

*

THERE is an epidemic of small buckles just now, which break out like an eruption all over women's garments. Stock collars are trimmed with them;

3799 Girl's Long Waisted Dress, 4 to 12 years.

waists are closed with them, and they often are spaced along beading or ribbon garniture. A pretty idea in silk waists is to have the garment close down one side, after the Russian model, the apparent fastening being little tabs of the material drawn through tiny buckles, and often a little metal dangler hangs from the buckle. The metal spike tags are very common now, but some ingenious women have finished the ends of ties or trimmings by using, in place of these tags, handsome old-fashioned ear rings. The long, drooping style of 30 years ago is just suited to such use. The end of the ribbon or material is neatly gathered and then tipped with the ornament.

*

SOME of the daily papers, in discussing the recent departure of an abnormally rich young husband and wife for a two-months' stay in Europe, proudly announce that their child is left under the charge of five competent nurses. The poor little rich baby, their firstborn, is two months old, and many young mothers, to whom a trip to Europe is a rainbow dream, would think it dearly bought at the expense of this separation. It makes one realize the idea thus suggested by two women quoted in the Youth's Companion:

"Yes, my dear," said one, "I knew him when he worked for Uncle Joe for $3 a week. Of course that is the fixed price for all millionaires who have made their money, and it does make one tired, but this is literally true. And now he has a house in New York, another at Newport, a farm on Long Island, an estate in Lenox and cottages at Tuxedo and Aiken, besides a yacht and a private car that is the apotheosis of leather and gilding."

"Where is his home?" asked the other.

"Home? He hasn't any. When they get as rich as that they've no more home instinct than milk cans."

The Rural Patterns.

Long-waisted effects are in the height of style for the little girls as well as for their mammas. The pretty little dress shown is suited to warm weather wear, but can be used with a guimpe and become high of neck and long of sleeve if desired. The material of the original is French nainsook, with a bertha of allover tucking and trimming of needlework bands, but all the cotton and linen fabrics are suitable as well as childish designs in China silks and such simple woolen materials as cashmere, albatross and the like. The waist is made over a fitted lining, which keeps it neatly adjusted. The backs are laid in tucks, but the front is simply gathered, and the neck is finished with a shaped bertha that is exceptionally becoming. The

3781 Five-gored Petticoat. 22 to 32 in. waist.

skirt is gathered at the top, finished at the lower edge with a hem, and joined to the body portion. With the frock is worn a sash of the material trimmed on the ends and simply tied in a knot. To cut this dress for a girl of eight years of age five yards of material 21 inches wide, three yards 32 inches wide, or 2½ yards 44 inches wide will be required, with ⅝ yard of all-over tucking for bertha, two yards of insertion and four yards of edging to trim as illustrated. The pattern, No. 3799, is cut in sizes for girls of 4, 6, 8, 10 and 12 years of age; price 10 cents from this office.

The foundation skirt or long petticoat that can be worn as a slip beneath unlined skirts is a necessity that every woman knows and feels. While it is always possible to make it exactly like the outer skirt the comfort and advantage of a model specially designed for the purpose, that can become interchangeable when desired, will be recognized at a glance. The admirable example illustrated is designed with direct reference to the needs of the season and is suited to both silk and lawn, which latter material is admirable as a foundation for organdies, batistes, Swiss muslins and all similar fabrics, but as shown is of taffeta with narrow frill and ruches of the same. The skirt is cut in five gores and is fitted smoothly and snugly about the hips, while the fullness at the back is laid in an inverted pleat. The flounce is circular and is seamed to the lower edge, while it, in turn, is trimmed with a bias frill 2½ inches wide, edged and finished with a tiny ruche, and is headed by a similar ruche that is slightly wider than those upon the frill. The upper edge of the skirt is simply faced or narrowly bound and so ensures a perfect fit about the waist. A placket is formed in the center back seam and the closing made invisibly with hooks and eyes, but gathers may be substituted and the top completed with a straight belt if so preferred. To cut this skirt for a woman of medium size 8¼ yards of material 21 inches wide or six yards 32 inches wide will be required. The pattern No. 3781 is cut in sizes for a 22, 24, 26, 28, 30 and 32-inch waist measure; price 10 cents.

LET the soul be turned as strenuously towards good as it usually is towards evil and you will find that the simple love of goodness will give incredible resources to the spirit in its search after truth. Love, with little intellect, will perform miracles.—Fenelon.

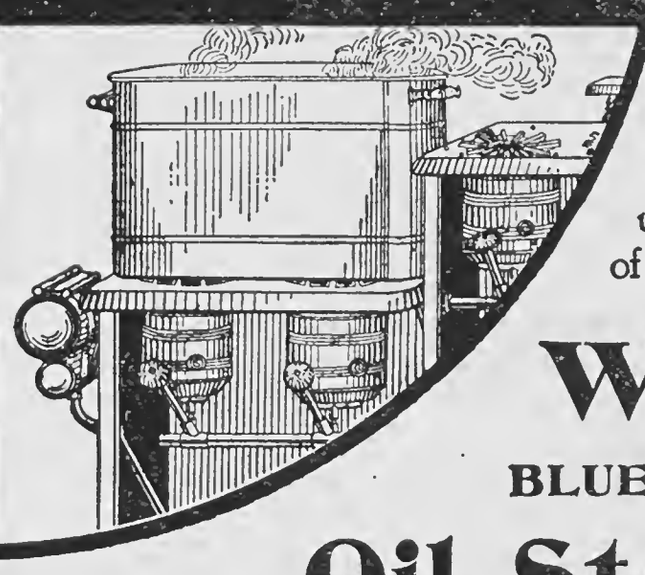
FROM WASHDAY TO BAKING DAY

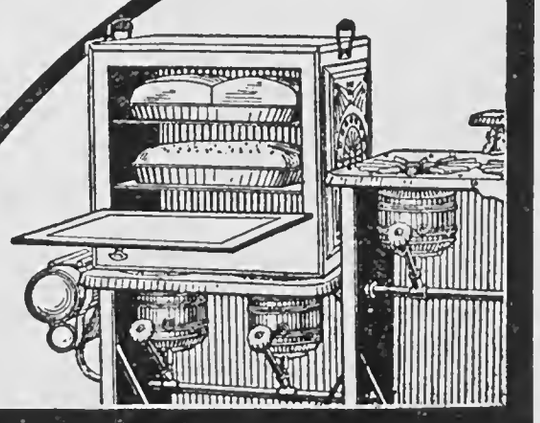


From Monday to Saturday—at every turn in the kitchen work—a Wickless Blue Flame Oil Stove will save labor, time and expense—and keep the cook comfortable. No bulky fuel to prepare or carry, no waiting for the fire to come up or die down; a fraction of the expense of the ordinary stove. A

Wickless
BLUE FLAME
Oil Stove

will boil, bake, broil or fry better than a coal stove. It is safe and cleanly—can not become greasy, can not emit any odor. Made in several sizes, from one burner to five. If your dealer *does not* have them, write to nearest agency of

STANDARD OIL COMPANY.



A Balsam Pillow.

PART I.

Now that fir needles and hemlock needles have become recognized articles of commerce, and every other shop now boasts its row of fragrant cushions, with their inevitable motto, "Give Me of Thy Balm, O Fir Tree," I am reminded of the first pillow of the sort that I ever saw, and of what it meant to the girl who made it. I should like to tell you the little story, simple as it is. It belongs to the time, eight or nine years since, before pine pillows became popular. Perhaps Chateaubriand Dorset may be said, for once in her life, to have set a fashion. Yes, that was really her name. Her mother met with it in a newspaper, and, without the least idea as to whether it appertained to man or woman, adopted it for her baby. The many syllables fascinated her, I suppose, and there was, besides, that odd joy in a piece of extravagance that costs nothing, which appeals to the thrifty New-England nature, and is one of its wholesome outlets and indulgences.

So the Methodist elder baptized the child "Chateaubriand Aramintha," making very queer work of the unfamiliar accents, and then, so far as practical purposes are concerned, the name ceased to be. How can a busy household, with milk to set, and milk to skim, and pans to scald, and butter to make, and pigs to feed, find time for a name like that? "Baby," the little girl was called till she was well settled on her feet and in the use of her little tongue. Then she became "Brie," and Brie Dorset she remained to the end. Few people recollected that she possessed any other name, unless the marriage, birth and death pages of the family Bible happened to be under discussion.

The Dorsets' was one of those picturesque, lonely, outlying farms, past which people drive in the Summer, saying, "How retired! how peaceful!" but past which almost no one drives in Winter. It stood, with its environment of red barns and apple orchards, at the foot of a low granite cliff whose top was crowned with a fir wood, and two enormous elm trees met over its roof and made a checkerwork of light and shade on its closely blinded front. No sign of life appeared to the city people who drew their horses in to admire the situation, except, perhaps, a hen scratching in the vegetable beds, or a lazy cat basking on the doorstep, and they would drive on, unconscious that behind the slats of the green blinds above a pair of eyes watched them go and a hungry young heart contrasted their lot with its own.

Hungry! There never was anything like the starvation which goes on sometimes in those shut-up farm houses. Boys and girls feel it alike, but the boys are less to the pitied, for they can usually devise means to get away.

How could Brie get away? She was the only child. Her parents had not married young. When she was 19 they seemed almost elderly people, so badly does life on a bleak New England farm deal with human beings. Her mother, a frail little woman, grew year by year less fit for hard labor. The farm was not productive. Poverty, pinch, the inevitable recurrence of the same things to be done day after day, month after month, the same needs followed by the same fatigues—all these Brie had to bear, and all the while the child had that love and longing for the beautiful which is part of the artist's equipment and the deprivation of which is keen suffering. Sweet sights, sounds, smells—all these she craved and could get only in such measure as her daily work enabled her to get them from that world of nature which is the satisfaction of eager hearts to whom all other pleasures are denied.

The fir wood on the upper hill was the temple where she worshiped. There she went with her Bible on Sunday afternoons, with her patching and stocking-mending on other days. There she dreamed her dreams and prayed her prayers, and while there she was content. But all too soon would come the sound of the horn blown from below, or a call from the house, "Brie, Brie, the men are coming to supper; make haste!" and she would be forced to hurry back to the workaday world.

Harder times followed. When she was just 20, her father fell from his loaded hay wagon and fractured his thigh. There was no cure for the hurt, and after six months of hopeless tendance he died. Brie and her mother were left together on the lonely farm, with the added burden of a large bill for doctoring and medicines, which pressed like a heavy weight on their honorable hearts.

The hired man, Reuben Hall, was well disposed and honest, but before Mr. Dorset's death he had begun to talk of going to the West, and Brie foreboded that he might not be willing to stay with them. Mrs. Dorset, broken down by nursing and sorrow, had become an invalid, unable to assist save in the lightest ways. The burden was sore for one pair of young shoulders to bear. Brie kept up a brave face by day, but at night, horrors of helplessness seemed as brass, against which her feeble prayers beat in vain, the future was barred, as it were, with an impassible gate. What could they do? Sell the farm? That would take time, for no one in particular wanted to buy it. If Reuben would stand by them, they might be able to fight it out for another year, and, what with butter and eggs and the corn crop, make enough for his wages and a bare living. But would Reuben stay?

Our virtues sometimes treat us as investments do, and return a dividend when we least expect it. It was at this hard crisis that certain good deeds of Brie's in the past stood her friend. She had always been good to Reuben and her sweet ways and consideration for his comfort had gradually won a passage into his rather stolid affections. Now, seeing the emergency she was in, and the courage with which she met it, he could not quite find the heart to "leave the little gal to make out by herself." Fully purporting to go, he stayed, putting off the idea of departure from month to month, and though, true to his idea of proper caution, he kept his good intentions to himself, so that relief of having him there was constantly tempered by the dread lest he might go at any time, still it was relief.—Susan Coolidge in Colorado Weekly Times.

Rhubarb Recipes.

Rhubarb is one of the most wholesome products of the home garden at this season, and some of the following recipes may be new to those tired of the stalks when stewed or made into pies:

Baked Rhubarb.—This requires less sugar than stewing. Peel the stalks, selecting red rhubarb. Cut into inch lengths and place in a stone crock. Add one part of sugar to two parts of the fruit, unless you like it very sweet, then add nearly half and half; arrange the fruit and sugar in layers; use no water. Stand the crock in a pan of hot water, cover and set in the oven and bake until the pieces are clear. This may be used for a meringue by filling a shell of good light pastry, covering the top of the fruit with a meringue and coloring a delicate brown in the oven.

Rhubarb Compote.—Cut red rhubarb into pieces three inches long. Cover with cold water and set over a moderate fire where it will very slowly come to the boiling point, but do not allow it to boil. Drain the water off carefully, or take the rhubarb up on a fork, keeping the pieces whole. Measure the water and to each pint add a pound of granulated sugar. Boil until it becomes a syrup, then pour over the rhubarb. This is nice served with plain boiled rice for a simple dessert.

Rhubarb Sherbet.—Wash the stalks and cut into pieces one inch long. To a dozen stalks add three pints of cold water. Cook in a double boiler until tender. Flavor with grated lemon or orange peel, and sweeten to taste. Let stand in a cool place for several hours, then strain and chill. Add shaved ice.

Rhubarb Cream Pie.—One cupful of rhubarb chopped fine or grated, one cupful of sugar, a pinch of salt, a grating of nutmeg or lemon peel. Moisten a tablespoonful of cornstarch with a tablespoonful of cold water; then fill the cup up with boiling water, stirring until clear. Beat the yolks of three eggs until light, and add them with the cornstarch to the other materials. Line a pieplate with good light paste, fill with the mixture and bake in a moderately hot oven until custard is set. When done and cooled, cover with a meringue made with the whites of the eggs and half a cupful of confectioner's sugar. Brown delicately in the oven.

Rhubarb Fritters.—Select the smaller stalks of tender, fresh rhubarb. Cut into pieces two inches long; cover with cold water and steam until tender; drain and spread on a platter. Make a syrup of sugar and water, flavor with a little lemon. Pour this over the rhubarb and let stand until perfectly cold. Drain off the syrup, dust the rhubarb thickly with granulated sugar. Make a fritter batter in usual way, dip the pieces of rhubarb in the batter and fry in deep hot fat.

Rhubarb Soufflé.—Pare and cut the rhubarb into small pieces, add enough water to keep from burning, and a pound of sugar to each quart of rhubarb. Stew until tender, then press through a sieve. Measure your rhubarb, and to each pint take three eggs; separate and beat the yolks very, very light, and add to the rhubarb. Mix well, then whip the whites to a stiff froth and fold into the mixture. Throw into a well-buttered dish and bake in a quick oven about half an hour. When it cracks open on top it is done.

Rhubarb Cobbler.—Fill a deep, buttered, earthenware pie dish with rhubarb cut into pieces an inch long. Make a batter of eggs, flour, milk and salt, allowing a large tablespoonful of flour to each egg and milk enough to make a batter thick as for fritter batter. Pour this over the rhubarb and bake until the pudding is light and nicely browned.

Rhubarb Tapioca.—Prepare the rhubarb as for stewing; place in a deep baking dish and add sugar enough to sweeten well, a little shredded orange peel, salt and dot with bits of butter. Add one quart of water to half a cupful of fine tapioca. Add a pinch of salt and cook in a double boiler for 15 minutes. Then pour over the rhubarb, cover the dish and bake half an hour. Serve with sweetened whipped cream.

With the Procession.

KNOW that strength is yours in proportion to your progress, enough for each day, be it mental, physical or spiritual. Realize that there is a reward for every labor, rest after every task, and rise for every faculty developed. Your reward may not be what you expect; probably it will be much better. The power which comes from trying is more than worth the effort.—Adelaide Keen.

A THING is worth precisely what it can do for you, not what you choose to pay for it.—Ruskin.

HE who can be true to his best and secret nature, who can by faith and patience conquer the struggling world within, is most likely to send forth a blessed power to vanquish the world without.—Martineau.

YOU are never quite conscious of how many disagreeable lodgers there are in that many-chambered mansion you call your "self" until anger or envy or hate knocks at the door—and presto! out come trooping such a lot of unhappy creatures—rancor and uncharitableness, and suspicion, and all unkindness, a perfect army of enemies to peace and happiness.—Helen Watterson Moody.

AFTER all we must come back to the old truism: that men and women are like water; they always find their true level. And where you live happiest, that is your level. There's polluted water, and there's clear water. But one law is inexorable: the closer you get to Nature, the truest and simplest thing there is because it is closest to God, the clearer always will you find the water.—Ladies' Home Journal.

THE circumstances that surround us at any given time are transitory, but they are the occasions of modes of life, thought and feeling, which are not perishing, the mortal mothers of immortal children. The immortality of a thought, a word, a deed! We can trace them back sometimes to the limits of memory. We are what they have made us. . . We forget the details, we feel the result. Suppose a plant endowed with consciousness, it is conscious of itself; it may not remember every ray that has warmed, every frost that has wounded it, yet each and all have contributed to make it just what it is, no more, no less, and of that whole it is conscious.—Eliza T. Clapp.

BUSINESS BITS.

THE Osgood Scale Co., Binghamton, N. Y., would like to have three or four good live men in every county to look after their interests.

A NEW implement for hilling corn, potatoes, cotton and tobacco, is offered by Van Allen Whitbeck, Aquetuck, N. Y. For hoed crops this should be a great labor saver. Write for circular and full information.

"HOGOLOGY" is a pamphlet on the care and diseases of hogs and their remedies. It is issued by Jos. Haas, V. S., Indianapolis, Ind., who has had 25 years' experience in treating diseases of hogs. The pamphlet and special advice for your particular case can be had for the asking.

THE letter below is a pretty strong endorsement for Tuttle's Elixir as a veterinary remedy. "Dr. S. A. Tuttle: I have used more than 100 bottles of your Elixir, and always with the best of results. I find nothing that will take its place in my stable. Will you please send me your horse book?" W. W. MORES.

Kingfield, Me.

To prove their confidence in their machines and to allow prospective customers full opportunity thoroughly to test them by actual use, the National Dairy Machine Co., of Newark, N. J., will send any dairyman one of their National hand separators for 10 days' free trial. Intending purchasers of separators will do well to send to the company for catalogue and particulars of the free trial offer.

THE line of compressed air sprayers offered by the Ripley Hardware Co., Grafton, Ill., commands the attention of fruit growers. The compressed-air feature has a great advantage over the old-style force-pump sprayers, and this company guarantees to fulfil every claim it makes for the implement, or will refund the purchase money. Circulars, prices and full information may be had for the asking. Address as above.

The Early Potato Crop.

THIS is the round and sweet potato section. Round potatoes are looking green over the fields. Some sweets are set out; weather cold and dry. S. J. C.

Cheapside, Va.

Our soil is a dark loam with a gravel subsoil, so we have natural drainage. I am pleased to report no rot or replanting, except a few low places where the water formed ponds. Acreage about as last year; early potatoes coming up. C. O.

East Williston, L. I.

I have an acre of swamp Hebrons planted April 11, in soil that is a sandy loam. The seed pieces were cut to one eye as a rule, and some of them are very small. One part of this acre is so low that I could not drain the water off it. In that particular spot the seed pieces are entirely gone, but elsewhere I failed to find any that were rotted. May 7 I counted three sprouts above ground. They were planted about three inches below the surface, and the ground was harrowed level. April 13 and 14 we planted five acres of Green Mountain and Carman, and April 17-18 we planted six acres of Sir Walter Raleigh and Carman on very heavy but well-drained loam, and a careful examination a few days ago failed to reveal any rot. The acreage planted in this vicinity is about the same as last year, but potatoes are planted very much later than last year, and late plantings as a rule have a hard time to make a showing, as the bugs find them even before they get out of the ground.

Syosset, L. I. J. S. B.

FRUIT CROPS.—The outlook now is good for a fine fruit crop this season. The apple and plum trees are loaded with blossoms. If there is no frost the prospect is good. The grass crop is looking fine for this time of year. The Spring was favorable for clover roots. The clover crop has been light here for the last two years.

Antwerp, N. Y. L. S. R.

THE present outlook is bright for small fruit; pears and cherries are blooming full; apple trees seem to be laying off this year, especially Baldwins and Greenings. Many other kinds are budding full. Only about one farmer in 10 sprays his orchard, yet all realize we must do it if we expect good fruit. I. S. J.

Otsego Co., N. Y.

So far the season is backward, with cold winds. Apples not forward enough yet (May 6) to tell. Plums, Lombard, will bloom full; cherries, what few there are, and pears I think the same. We had plenty of rain so far, and grass is looking well for this time of year, but winds are cold. Some have finished seeding; others not commenced back on hills where ground is naturally moist. A. H.

Sherburne, N. Y.

During the sixty-two years that Dr. D. Jayne's Expectorant has been used in the treatment of Pulmonary disorders, the percentage of cures has largely increased. Undeniably, IT HEALS THE LUNGS.—*Adv.*

Wants, For Sale or Exchange

FOR SALE.

Country Home, "Rural Grounds,"

of the late ELBERT S. CARMAN, for many years owner and editor of The Rural New-Yorker.

Situated in the Hackensack valley, 18 miles from New York, one mile west of the station, River Edge, on the New Jersey and New York Railroad. House in excellent order with broad piazzas. Good stable and carriage room. The grounds, consisting of a little over two acres, are beautifully graded and planted with rare coniferous and deciduous trees and shrubs. A never-failing lake of pure spring water adds to the beauty of the grounds.

MRS. ELBERT S. CARMAN, of No. 5 West 82nd Street, New York, will answer questions and show views of the place

Farm Managers, Gardeners, Buttermakers, etc., always on hand. No charges to employers. Write us. Rural Science Agency, Durham, N. H.

100 FOR SALE WESTERN RESERVE FARMS in the Mahoning Vy. Send for list. Dennison & Miller, Warren, O.

FARM IN VIRGINIA completely stocked and equipped for $5,500. 231 acres smooth, fertile land; well watered; thoroughly fenced; large bearing orchards. New 8-room residence; ample outbuildings; elegant Mountain views; near town and depot. Very attractive. $5,500. Send for details. Box 282, Lynchburg, Va.

COMPETENT GARDENERS.—The comforts and products of a country home are increased by employing a competent gardener; if you want to engage one, write to us. Please give particulars regarding place and say whether single or married man is wanted. We have been supplying them for years to the best people everywhere. No fee asked. PETER HENDERSON & CO., Seedsmen and Florists, 35 and 37 Cortlandt St., New York.

Two Grandsons of Exile, sire of 86 tested cows. Solid Color, one and three months old. Handsome. J. A. HERR, R. D. No. 4, Lancaster, Pa.

Seed Potatoes—Rural New-Yorker and Sir Walter Raleigh, 50c. per bu., sacks or bbls. included. O. E. WHITTEN, Bridgman, Mich.

Oldest Commission House in New York Est. 1838. Butter, Cheese, Eggs, Pork, Poultry, Dressed Calves, Game, etc. E. B. Woodward, 302 Greenwich St., N.Y

GEO. P. HAMMOND. EST. 1875. FRANK W. GODWIN.

GEO. P. HAMMOND & CO.,

Horses, Cattle, Sheep and Swine

$2 Book for $1

We have yet some copies left of a lot of slightly shelf-soiled books of **Horses, Cattle, Sheep and Swine,** by Curtis, that we will mail postpaid as long as they last for $1. This book is the standard work on live stock. It is used as a text-book in almost all agricultural colleges, and is indorsed by all leading authorities on live stock. It is a large book, fully illustrated, and requires 16 cents to pay postage alone. These copies are in condition for any library, and will be reserved for subscribers alone. They will not be sent at this price to dealers. They are a great bargain at the price for anyone who wants to make a study of animal husbandry.

THE RURAL NEW-YORKER, NEW YORK.

Market Briefs.

PICKED UP HERE AND THERE.

LAKE TRAFFIC.—The American and Canadian canals connecting Lakes Superior and Huron, are the highways over which large quantities of merchandise pass during the season. For the month of April 104 vessels passed through these canals, either east or west, carrying a total freight of 2,545 tons. The largest single item was grain—23,500 bushels.

APRIL FIRE LOSSES for the United States and Canada amounted to $11,352,800, less than half the loss for the same month last year. The Jacksonville, Fla., disaster, which will be figured in the May report, will about bring up the total for the first five months to that of last year. The largest single item for April was $650,000 for a St. Louis grain elevator. Most of the fires ranged from $10,000 to $75,000.

THREE NEW TRUSTS.—Straw hats, oilcloth and music are now applying for enlistment in the army of combinations. If the exactions of the first two become too oppressive, we may have to go back to the bare-headed and sanded-floor modes of living of our ancestors; but we understand that the music trust is not to take in the hand organ, horse-fiddle and squeejunk, so there is no immediate danger of a musical famine for those who decline to patronize this proposed monopoly.

HEAVY LEMON SALES.—A Mediterranean steamer loaded with oranges and lemons has arrived at Montreal, Canada, and the cargo is being disposed of at auction. On May 7 about 100,000 boxes of oranges and lemons were sold, prices for the latter ranging from $1.35 to $2.75 per box. New York lemon dealers were on hand and bought heavily. The oranges did not sell well. California lemons, while of good quality, do not take the place of those from Sicily. Analyses have shown that the latter contain a larger pereentage of citric acid, which is thought to be due to peculiar conditions of soil and climate.

WASTED LABOR.—Some apple packers have queer ideas. In one commission house was seen a barrel of inferior Greenings, every apple wrapped in tissue paper. The man who sent them evidently thought that the paper and extra work done would sell the poor fruit for a big price. The apples should have been sold in the early Winter. Many of them were partly rotten, and the dealer said he had not been able to get an offer for them. It is a pretty safe rule to sell Greenings in the Fall, as they do not keep well, and will not stand handling. Those who wish to hold apples for a late market would better depend on Newtown, Baldwin or Ben Davis.

PLENTY OF ONIONS.—On the White Star Line steamer Georgic, from Liverpool, is an uncommonly large shipment of onions—nearly 17,000 sacks, valued at about $40,000. Old domestic onions are scarce, and this causes an increased trade in Egyptian stock. Quite a percentage of the onions received here are consumed by the foreign population, particularly the Italians, who use them in combination with red peppers in a variety of ways. They also work well in stews or hash in the type of eating houses where a man who has a steak for supper is quite likely to renew his acquaintance with the tough and uneatable portion in the hash he has for breakfast.

THE MAN WHO LEANS.—He is found in crowded street cars, and is apparently so lacking in common sense and decency that he sees no impropriety in leaning against his neighbor, whether man or woman. He is usually well-dressed, and a big, able-bodied man, muscular enough to hold himself up. The one remedy is to let him lean for some time, then suddenly move to one side and note his wild efforts to keep from falling. This trick was neatly done in a Broadway cable car. The car was not crowded, there being room enough so that those who were standing need not have brushed against each other at all. One of these hogs was reading a paper, and instead of hanging on a strap, leaned against another man, who stood it for a time. As the car neared one of those sharp curves, around which they go so swiftly as almost to throw people out of their seats, he got a firm hold of the strap, and as the car flew around the corner, he lurched to one side, so that the leaner fell flat on his back, to the amusement of the other passengers.

HEAVY TRADING.—The business done on the New York Stock Exchange for the past month has been enormous. More than 630,000 transactions were recorded in a single hour, and the brokers' commissions for buying and selling in one day amounted to nearly $400,000. Demoralizing as some aspects of this business are, it does not merit the wholesale condemnation heaped upon it by those who denounce all Wall Street operators as cutthroats and thieves. It is true that unusual opportunities are given for taking advantage of the ignorance or misfortunes of others, and the loser is often ground into the dust in a way that seems heartless, yet these are not the methods of all Wall Street men. The effect of such a boom in stocks is bad on many young people, clerks and stenographers, both men and women. They see how the investment of $100 on a margin may in one day bring them more money than they could earn at their work in months, and take the risk. In many cases the worst thing that can happen to them is to win, because after one taste of easy money-making, they will never be satisfied with the slower method of getting what their labor is actually worth. No young person knows the value of a dollar or how to spend it wisely unless he has earned it by work. The conversations overheard at this time between young men in street cars and restaurants indicate that the one thing uppermost in their minds is stock speculation. W. W. H.

A Good New Apple

I am the ardent champion of fine-flavored fruits. Nurserymen often fail to grow deserving varieties because they do not make straight young trees, so they do not "deliver well." The Mann apple is a well-known instance of a very poor apple sent all over the land for the reason, as I happen to know, that the young trees grew straight and "delivered well." Good quality is the only criterion of merit. Last Autumn, while gathering a collection of 100 varieties of Winter apples for an exhibit of northwestern Michigan fruits at the Pan-American Exposition, I found a Kalkaska County apple I named Wolverine, which is the greatest hustler and barrel-filler of any apple I know. It was first spoken of in public and exhibited at Michigan State Fair in 1900. It bloomed at four years from seed, and has been heavily loaded every year for sixteen years without fail, and with its cloud of big leaves and large white blossoms, it gets there in spite of cold weather, having passed through 40 degrees below zero unharmed. This and another new variety will probably be exhibited at Buffalo. I visited Olivet in search of scions of favorite apples of my school days; Early Joe, the finest early; Primate, Dyer, Sops of Wine, Gravenstein, Ohio Nonpariel, and McDonald, the last a seedling. Four years ago, when I was engaged in buying apples at Lee, a seedling tree bore a heavy load of smooth, light green apples, with a deep red cheek. These I called Van's Blush, and they sold readily. As I approached the tree recently, behold a pile of brush made of its once symmetrical top, and firewood sawed and split out of the smooth body. The storm had uprooted it, and thus the history of another new apple seemed ended.

Charlevoix, Mich. F. M. B.

Hudson River Fruit Transportation.

On May 3 the transportation committee of the Eastern New York Horticultural Society and representatives of other organizations met at Newburg, N. Y. Among those present were J. A. Hepworth, Chas. Forster of New York, J. S. Hosford, J. S. Carpenter, E. R. Martin, E. B. Covert, J. R. Clark and H. W. Collingwood. They first called upon W. H. Weston, president of the steamboat line which carries a large proportion of the fruit of that section to New York. No time was lost in making known their chief wants, which are: More careful handling of fruit; better service in returning empty crates.

Shippers who were present described the way in which deck hands sometimes play ball with crates or boxes of fruit. They seemed to convince Mr. Weston that they knew what they were talking about, and that reforms are needed. Chas. Forster corroborated the statements made by shippers—in fact, there was no chance for an argument, and Mr. Weston agreed that more careful service must be given.

The empty crate question is an old one. At present the crates are brought back and dumped—none too carefully—on the dock. Each fruit grower is supposed to help himself from the pile. The result of this careless system is that some men get more than their share, while others are short just at the time the crates are most needed. Sometimes a man will order 100 crates from his commission man, only to find that some neighbor has come in ahead of him and taken half or more for his own use. It is easy to see how much confusion and trouble this lack of system means. The fruit shippers want their crates sorted and piled so that each man may get his own and give a receipt for them if necessary. In other words, they want these crates carried and handled like other merchandise. They cost money and are a necessary part of the business. If it be said that they are carried for nothing, the answer is that more than enough is paid for carrying the full crate to cover the round trip. These things were made so clear and plain at the meeting that there can be no chance for an argument. Mr. Weston certainly talked fairly, and seemed disposed to do his best to improve the service. The men who were present represented a good deal of freight, and all of them understand the situation and the remedy, if needed.

The committee also met P. K. Bushnell, representative of the National Express Company, and told him in a business-like way what was wanted. He promised that crates would be returned promptly and in good shape, and properly delivered. He also guaranteed quick and careful service in handling fruit. We think this was a good day's work for the fruit growers of the Hudson River Valley. Much of the credit is due to J. A. Hepworth of Marlborough, the chairman of the committee. This work simply shows what would happen if any large proportion of fruit men in the valley would fall in behind the committee and push hard.

CUTTING SMALL POTATOES.—Planting seed ends of small potatoes certainly does not pay. For 15 or 20 years, when using small seed of long varieties, I clip the seed end and throw it away, and divide the remainder into two pieces. This method, by several trials, has given more merchantable and less small potatoes than would be the result if all were planted. Small seed, hen's-egg size, for instance, has too many eyes unless cut too small. A good-sized piece with two good eyes with us is just right. Whole seed is sure to give a multitude of small and few large tubers. We plant with an Aspinwall planter. B. B.

Hopeless and Helpless.

The consequences of a diseased condition of the stomach and digestive and nutritive system are most disastrous to the whole body. One by one every organ may become involved. The misery is maddening. The most extreme cases of "stomach trouble" and the evils resulting from it have been cured by Dr. Pierce's Golden Medical Discovery. It strengthens the stomach, purifies the blood and builds up the body with sound healthy flesh.

"I was taken with severe headache," writes Thomas A. Swarts, Box 103, Sub-Station C, Columbus, Ohio, then cramps in the stomach, and my food would not digest, then kidney and liver trouble, and my back got weak so I could scarcely get around. I just gave money to the doctors whenever I thought they would do me any good, but the more I doctored the worse I got until six years passed. I had become so poorly I could only walk in the house by the aid of chair, and I got so thin I had *given up to die*, thinking that I could not be cured. Then I saw one of my neighbor boys and he said, "Take my advice and take Dr. Pierce's Golden Medical Discovery and make a new man out of yourself." The first bottle helped me so I thought I would get another, and after I had taken eight bottles in about six weeks I was weighed and found I had gained twenty-seven (27) pounds. I have done more hard work in the past eleven months than I did in two years before, and I am as stout and healthy to-day, I think, as I ever was."

Dr. Pierce's Pleasant Pellets cure biliousness.

NATIONAL
HAND SEPARATOR

You needn't run the slightest risk in buying a separator. Get a National Hand Separator and do your skimming with it for ten days

ABSOLUTELY WITHOUT COST

You won't be under any obligation whatever to buy it.

Test the National by the side of any other separator made. If you don't say the National is the best machine we'll take it back cheerfully. Write now.

National Dairy Machine Co.
Newark, N. J.

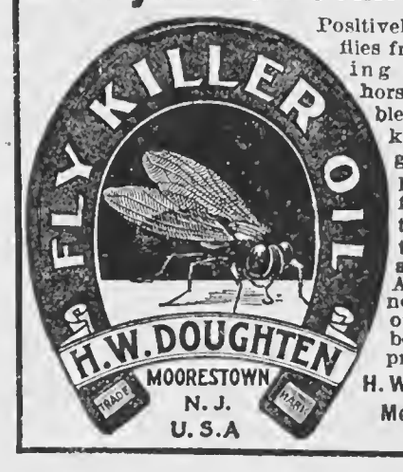
The Farmer
Can Reduce Expenses

of cultivation by the judicious use of

Nitrate of Soda

upon his land. This when properly applied, with other elements of plant food, never fails to largely increase the yield of hay, grain, or garden crops, without additional cultivation or labor. Our literature and ***list of dealers*** in *Nitrate of Soda* will be sent free on application to **John A. Myers,** 12-O John St., New York City.

Make your Cow Comfortable



Positively prevents flies from annoying cows or horses; rids stable of flies, keeps stock good tempered and in fine condition. A boon to every stock owner. Apply to your nearest dealer or write for booklet and prices.

Moorestown,
N. J.

Gold-Shell Rings.

Most people like a nice ring. We show three styles. These are made by drawing a shell of gold over a rod of composition metal. They are better and will wear longer than solid gold rings of a low carat. The retail price would be from 75 cents to $1. We will send one of these rings postpaid as a reward for sending one new subscription at $1. Cut a slip of paper the size of finger and send for size.

The New Horticulture

BY H. M. STRINGFELLOW.

We do not hesitate to say that this is one of the most interesting books on horticulture that ever was printed. Most reading farmers have heard of the now famous "Stringfellow Method" of planting trees, but few understand clearly what it is. This book tells the whole story in clear-cut, forcible style, which all can understand. Not only is the theory of close root-pruning carefully explained, but the general principles of gardening and fruit-growing are discussed. Mr. Stringfellow is a practical gardener, and he gives his own experience. We commend the book to all without reserve. New Edition, paper covers, 50 cents.

Live Stock and Dairy

THE BREEDER'S WAYSIDE.

The Number of Pigs to the Litter.

How large a litter of pigs should a sow farrow? That depends. A young sow should not have as large a litter as a mature one. A sow in poor condition during pregnancy should have a smaller litter than one in strong breeding flesh. Each mother should be in such bodily condition as would best enable her to stand the drain of suckling her offspring. Immaturity or unsuitable condition calls for relatively small litters. If a sow has the capacity to produce ample milk to suckle eight pigs until 10 weeks of age, and keep them growing strong and healthy, then it is a loss to the breeder if she kills a part of her litter, or farrows any number less than eight. The most profitable use of any sow calls for the production of the greatest number of pigs possible, which may be reared without detriment either to them or the dam. A good brood sow will, of course, usually lose in flesh while suckling a full-sized litter, but this is not to her disadvantage, as it is a perfectly natural operation. As soon as the pigs are weaned, she will rapidly take on flesh if fed sufficient food. Before weaning, her appetite is greatly increased, so that she consumes enough more food to supply her pigs from this increased consumption.

Personally, I desire a sow in her first litter to farrow at least seven. She should produce these at about 12 or 13 months of age. In her prime I consider a litter of 12 as large a number as she should ordinarily suckle to weaning time, though some sows are capable of handling more. From these larger litters any inferior, undersized runts should be destroyed, and only vigorous, growthy pigs kept for suckling. In fact, runts from any litter should be destroyed. Sows that farrow only four or five to the litter are not doing satisfactory breeding service. This condition usually occurs with short-bodied, chunky sows. The better type of brood sow should be fairly long-bodied, on short legs, and with deep sides. Her back should also be strong and straight, sagging being very undesirable. Her mammary development should be superior. While suckling, the glands of the udder ought to be shapely, with teats of good size, so that the pigs shall be able to suckle easily. A person does not usually need to keep brood sows with little short teats, or with milk glands of a defective character, where pigs have to work hard to obtain nourishment. People do not often enough take note of this important feature of the brood sow.

Now the question arises, should a person producing pigs for breeding purposes prefer a smaller litter than the one breeding for feeders? I see no reason why there should be any difference here. In either case, the pigs should be kept growing as fast as possible while suckling. The real difference in handling comes in after four months of age. Then the pig designed for the pork barrel may begin to have a greater fattening food than the one to be used for breeding, and at six months of age the diet of the two groups of pigs should be materially different. The lard pig of to-day, the chubby, dumpling sort, is deteriorating. Litters are becoming far too small, and profits are thereby lessened. Our breeders should look for a growthier, more productive pig in offspring. This oftentimes means the difference between profit and loss. There are certain individuals that farrow much larger litters than others, and by selecting from these one may develop a strain that will do far better in farrowing than selecting indifferently. In purchasing purebred pigs, buyers will be wise to ascertain the size of litters from which stock is offered them. Records of this sort are kept by all breeders of importance, and are filled with registration papers of pigs recorded. C. S. PLUMB.

Trumansburg, N. Y.

THE CARE OF INCUBATOR CHICKS.

I have fair success in hatching incubator chickens, but when one puts 50 or 75 nice lively chicks in a good brooder and gives them good care, and as it seems to me treats them "according to Hoyle" and they die by the two, three and four, one is naturally disheartened, and not willing to give up, I begin to look around for sources of information and advice. They stand around, sleepy-looking, and the next one knows they are dead. The eggs are laid by Golden Wyandottes, and Barred Plymouth Rocks, and the hens appear healthy, though confined in yards. I have fed these chicks oat flakes and some johnny cake made with chick-size grit in it, and they have grit and charcoal by them most of the time. Sometimes they droop and die when only a few days old, and again at a month old. They always seem hungry. M. W.

Patterson, N. Y.

Your information is rather meager of details concerning the care and food of these birds and their symptoms. If they hatched in good form the breeding flock is all right. Fifty per cent in chicks from incubator eggs is considered fair. They should, when due, come out prompt and lively; not drizzle along a few at a time, struggling out feebly. It is presumed that these were out with a rush. They should be very carefully changed to the brooder and not chilled; the heat kept as near 90 degrees as possible for the first week. Also, they need air, plenty. My brooder covers are both open a little and we enlarge the space as the birds grow older and the weather moderates. As the chicks absorb the yolk of the egg the last thing before they break from the shell, they are provided with food for 48 hours. The best plan is to leave them in the incubator two days after the hatch (if it is over on the twenty-first clean out the trays, but leave the chicks in the machine till the morning of the twenty-third). Have the front of the brooder covered with sand, and crush up your eggshells fine and scatter over. Have the chill off the drinking water, and if you put in a pint about five to 10 drops tincture of iron, it will prevent, so it is claimed, the "pasting-up behind." Let the chicks drink and pick at the sand till the afternoon, and then give them their first feed. Bread crumbs moistened and squeezed dry in milk are good, and cracker crumbs—but get them into hard food grains—so they can scratch and exercise soon as possible. Of course they need a variety of food, and many methods are advocated, but the main point is not to overfeed at first, or force them by too high temperature and too strong diet. They will perhaps stand it for the first three weeks, then they begin to die off like poisoned flies.

If they are anywhere near your breeding flock, or if you put with them chicks hatched under a hen, your babies will surely have lice. The "standing round, sleep-looking" sounds as though this is the trouble. There is a large gray louse on the head that bores into the brain and kills the chick. Mix up equal parts of melted lard and kerosene oil and rub a little in on the head and under each wing and around the vent; not enough to daub the bird up. Also, the insect powders are good and useful. After the first week begin to lower the heat in the brooder so that at the close of the second week it is 80 degrees, and at the end of the fourth it is 70 degrees. Four times a day is enough to feed; make them scratch for the early morning; then a mash, just what is eaten up clean, and the other two feeds grain in the litter, a generous supply at night. Oat flakes are good, but some way what suits one flock does not always do as well with another. I find it so with my ducks. If they don't seem to thrive and do well on one kind I substitute another. Bone meal and grits always at hand for them and green bone or beef scraps may be fed when 10 days' old, five per cent of the bulk of their food, gradually increasing to one-tenth when three months old. A close study of the ways of the hen with her little ones helps greatly in successful artificial rearing of chicks. F. E. W.

Chazy, N. Y.

THE "ROOTS" ON A HOG.

What can I do to stop my hogs from rooting up their pasture? I have rings in their noses, but still, when the ground is soft, they tear it all up.

I find that hogs are sometimes troublesome to control against rooting in wet weather. I have found that when they are rung well back in snout, so that the twisted end will not turn out of its naturally projected place, when trying to root it is much better than when not set back so far. In this way the projecting part is generally held in place and is the cause of keeping their noses somewhat sore continually while trying, thus causing disgust on the part of the hog soon. The instrument I see advertised as cutting out the center of the end of the hog's snout, I should think effectual. ARTHUR J. M'CAIN.

Delaware, N. J.

It is natural for a hog to root in soft, damp ground, and when it is in that condition I don't think ringing or clipping the end of snout any use. I keep our Berkshires off the pasture when the ground is soft. *Never ring or clip snout.* When the ground is reasonably hard and pasture good I turn out the Berkshires—first drawing a load of two of coal ashes with a barrel of salt mixed with them to the pasture lot. This mixture the hogs root over, finding what their systems require to tone up the stomach; then feed some grain, and we never have any trouble in having pasture rooted up only in soft, damp spots, which they will root over to wal'ow in.

Trumansburg, N. Y. R. H. STONE.

"Ed" Blair, of Cadmus, Kan., known locally as "the melodious poet of the Osage," has written the following lines on the hen:

Cackle, cackle, Plymouth Rocks,
Ye can have the wagon box,
'N' the smokehouse, 'n' the barn,
Take 'm—we don't care a darn.

Cackle here and cackle there,
Lay your eggs just anywhere,
Every time ye lay an egg,
Down the mortgage goes a peg.

Cackle, cackle, all the day,
Who kin find a better way
Fer to glt ahead again
Than to cultivate the hen?

BROOD SOW NOTES.—If sow is a good eater, and by good feeding gets thin with a medium sized litter (seven to eight pigs) and pigs are growing well, the sow is a good milker. If sow keeps in good condition with medium litter and pigs are not gaining well, she is a poor milker. About every sow gets thin, suckling a large litter, but a good milker gets very thin. A brood sow that is a poor eater is no good, and I would not keep her long. C. J.

Curb, Splint,

contracted cord, thrush, grease heel and all forms of lameness yield readily to

Tuttle's Elixir.

Used and endorsed by Adams Express Co.

Reading Trotting Park, Mass., Aug. 31, 1899.

Dr. S. A. Tuttle, V. S.

Dear Sir:—I want to add my testimonial to your list recommending Tuttle's Elixir for curbs, broken tendons, thrush, and nails in the feet. I have used it on all of these cases many times, and never failed to make a cure. J. H. NAY.

Given internally it is sure cure for **Colic, Distemper, Founder, Pneumonia, etc.**

TUTTLE'S FAMILY ELIXIR cures rheumatism, sprains, bruises, etc. Kills pain instantly. Our 100-page book, "Veterinary Experience," **FREE.**

Dr. S. A. TUTTLE, 30 Beverly St., Boston, Mass.

Beware of so-called Elixirs—none genuine but Tuttle's.

Avoid all blisters; they offer only temporary relief if any.

Breeders' Directory

HIGH-CLASS
Registered Jersey Cattle.
ROBT. F. SHANNON, Pittsburg, Pa.

JERSEY BULLS—Have on hand a few selected Registered Jersey Bull Calves, from two to four months old, from great milk and butter-producing dams, and of the most approved breeding. Improve the quality of your milk and butter output by taking advantage of this offering. We breed for quality and quantity. Will make price low; delivered to your station. Don't miss this opportunity. Correspondence promptly answered. WHITE OAK RIDGE STOCK FARM, East Orange, N. J.

FOR SALE—THOROUGHBRED HOLSTEIN BULL CALVES. Well marked and of best breeding. Will be sold at farmers prices. Write at once. W. W. CHENEY, Manlius, N. Y.

Holstein-Friesian Bull
ready for service, and a fine lot of Bull Calves. Best of breeding, and from deep producing families.
C. K. RECORD, Peterboro, N. Y.

150 DeHlhurst Holsteins
for sale, including young Cows, Heifers and a great lot of BULL CALVES—several now ready for service—sons of "DeKol's Butter Boy", and the famous "Royal Paul" out of advanced Registry cows. Catalogue.
DELLHURST FARM, Mentor, Ohio.

Reg. P. Chinas, Berkshires and *O. Whites*, Choice Pigs, 8 weeks old, mated not akin. Bred Sows and Service Boars. *Poultry.* Write for *hard times prices* and free circular.

Veterinary Pixine

has come to the front. There is not to be found in the materia medica a preparation of such penetrating, absorbing, soothing, antiseptic healing power. Seemingly incurable or aggravated chronic cases of scratches, grease heel, mud fever, old sores, inflammatory swellings and skin disease can be positively and permanently cured.

Money back if it fails.

2 oz., 25c.; 8 oz., 50c.; 5-lb. pkge., $4.

At all Druggists and Dealers, or sent prepaid

TROY CHEMICAL CO., Troy, N. Y.

DAIRY AND FARM NOTES.

WINTER WHEAT.—I am surprised at the outlook for our Winter wheat crop. Last year the Winter was not as favorable as I judged it, and we harvested 30 bushels to the acre. Lewis County is not a Winter wheat-growing section. Last Fall we seeded 45 acres and looked for a good stand. The ground was covered before freezing, and snow remained on till warm Spring weather took it away, and but little freezing and thawing subsequently. The stand is, to my surprise, not good. It apparently smothered worst where the snow was deepest. One small piece of two acres was sown about a week before snow and Winter came. It is the only perfect stand.

BUYING CLOVER SEED.—I am tempted strongly to reduce the amount of clover to the acre this Spring. It seems like a big bill to pay, and cheese prices two cents lower than last year. I am trying to convince myself, and have a clear conscience, that seeding in former years has been too heavy. The truth has finally conquered, and a few figures showed that I could not possibly save more than 30 to 40 cents an acre, and that would buy just three pounds of nitrogen either in cotton-seed meal, dried blood or nitrate of soda. Two years ago we failed in northern New York to get a catch of clover. Thousands of dollars have since been spent by the farmers in payment for gluten feed and other protein foods to take its place.

PURCHASED PROTEIN.—The growing of protein on our farms is the burning question to-day for the eastern farmer. This continual purchase of such an immense quantity of gluten, linseed, brewers' grains and other protein food is getting burdensome. The seller of milk in the East is often accused of drawing a can of milk to the station and a bag of feed from the mill to the barn. No statistics are at hand to show the amount of cattle food shipped into a locality for a period of years. But in the old milk shipping sections of Orange Co., N. Y., feed has been purchased liberally for years, and the soil should have steadily increased in its crop-producing power. I was interested last Winter in making inquiries at Pine Bush, Unionville, Washingtonville and Bloomingburg, when attending institutes, whether or not the farms were yearly increasing in fertility. The great majority of answers were in the negative. A ton of milk contains $2 worth of plant food, all removed from the farm. As near as I can compute, 500 pounds of protein food will be purchased for its production; in the Winter much more, but in the Summer much less. The plant-food value of this 500 pounds will average $2.50 at a careful estimate, and often, when cotton seed is fed, perhaps double this amount. The farm is therefore receiving more in plant food than it carries away, *if* all is saved. The *if* is the trouble. No section of the East is free from this extravagant waste in stable manure. Far-famed Orange County, just mentioned, is guilty as well as northern and western New York. We have been buyers of feed on our farms, perhaps too extravagant. We have the satisfaction, however, of seeing a gradual but constantly increasing production. Two causes are responsible for the increase; a careful husbanding of the manures, using absorbents, and getting the manure to the field as soon as possible. Increasing fertility not only provides for larger crops of corn and hay—the great backbone of dairy feeding—but enacts an enabling clause for the culture of the protein crops. What shall they be? For New York latitudes oats, peas and Red clover, with Alfalfa where it will thrive. No more satisfactory ration can be compounded than 30 pounds of silage, not too rich in corn, six to eight pounds of oats and peas ground, and as much clover hay as the cow will clean up and still think she would like a little more, all grown on our own farms. Available fertility must be at hand to do it.

NEW PASTURES.—Cows are being turned to pasture in some localities as I write, where a most scanty subsistence will be furnished for two or three weeks, and too often all indoor feed will be withheld; a serious mistake. I know of farmers who repeat it year after year without learning the lesson. Of course they are short of feed. Then for the cows' sake, if for no economic reason, either grow more silage corn or sell cows. Keep up the hay, silage and grain feed for the cows. I prefer hay and grain rather than silage at this time; we need to keep the bowels in proper condition, and hay aids much in neutralizing the looseness of the bowels. We have fed many different grains and mixtures. I am inclined to prefer wheat bran or oats. The succulent grasses are not muscle-producing. The cows have been standing quiet during the Winter, and when they are allowed their liberty or required to walk long distances in search of food, they need a muscle-producing food. Nothing supplies the want as well as oats. Wheat bran is usually cheaper; that is, the protein content costs less. It is, however, a narrow food, and does not therefore balance the grass food. The oats contain more carbohydrates and the nerve-producing element as well.

GARGET TREATMENT.—It is also a dangerous time for garget. Garget comes, I am satisfied, from a cold more often than we are ready to admit. The udder, which has come in contact only with a well-bedded warm floor, is altogether too sensitive to come in contact witn cold, damp ground. Said one of our foremen a few days ago: "A man needs to be a V. S., understand all about foods, and their effect, have patience and the ability and disposition to work hard every day in order to take care of a dairy." That's about it. The observation was brought about by a case of garget. Dr. Smead, the well-known institute worker, and V. S., of our State, first gave me the presently accepted remedy for parturient apoplexy, and it occurred to me that it might also be used without danger for garget. We have used it with some success: One-half ounce iodide potassium dissolved in one pint boiled soft water, using it as an injection for each teat, or one-quarter of it for one teat; one-half for two teats. I give this for what it is worth. Garget has been a most difficult disease to treat, because the animal becomes fevered and affected through the whole system before the owner is aware of it. Be careful that your cows do not take cold during the month of May. If the cows are not fleshy add a quart of cornmeal daily to keep up steam.

SHELTERED COWS.—Cows should be kept indoors nights until the ground is warm, and then it's my candid opinion that they are very much better off on the ground than in the barn. There is certainly a limit to artificial conditions; constant stabling, heavy feeding—in other words forcing the cows to work under milk pressure all the time—is not wise. The old custom of outdoor exercise for eight hours a day has been followed by an indoor extreme. We have one stable full of cows, 50 or more, that have been working too hard the past Winter, and they will have to take a rest. One grade Holstein, a 10,000-pound cow, has given milk continuously for several years. She has now taken matters into her own hands, and dried up completely six months before she is due to freshen again. From past experience of this kind I expect this cow has done her good work. She is getting very fat on hay and silage. We shall keep her and report later. The advocates of wholly artificial conditions, close housing, etc., are honest in their conviction, but their judgment has been based upon premises entirely different from the surroundings of most farmers who rear their own stock and keep a cow as long as she is profitable.

H. E. COOK.

LARGE USERS OF CREAM SEPARATORS

EVERY large user of separators in the country is now using and buying De Laval machines exclusively. Nearly all have tried various "cheaper" separators and cast aside thousands of dollars' worth of them. The same thing is true in Europe and throughout the world.

The dairy or farm user may well profit by experience of such large users. The difference between a superior and an inferior separator are just as material on the farm as in the creamery. But the small user may be hoodwinked or fail to appreciate the difference while the big user can't long overlook it.

Send for a 20TH CENTURY catalogue and see for yourself what the big users of separators are doing.

THE DE LAVAL SEPARATOR CO.

RANDOLPH & CANAL STS., CHICAGO. | General Offices: 74 CORTLANDT STREET, NEW YORK. | 1102 ARCH STREET, PHILADELPHIA.

103 & 105 MISSION ST., SAN FRANCISCO. | 327 COMMISSIONERS ST., MONTREAL.

Sharples "Tubular" FARM Cream Separators

Fifty Dollars for a High Grade Sharples Separator is Taking Them Off Like Hot Cakes.

The Buttercup is a beautiful separator of the Tubular type, handling 175 lbs of milk per hour to perfection. Its bowl is a plain tube only 2 inches in diameter and weighs a couple of pounds. Even a small pan of milk can be put through profitably and washing up will require but two or three minutes. We originally thought to name it the "Finger Separator," it turned so easily with one finger. It does its work perfectly, giving thick or thin cream, of smooth, velvety character, finest for table use or butter making.

Tubular Hand Separators and Steam Driven Separators for large dairies are the delight of every user, they require so little power, skim so clean, and are so simple, easily washed and kept in order. We warrant them to give enough more butter from the same milk than any other separator, to pay over 6% interest on their whole first cost. A free trial to every one. Book, "Business Dairying," & catalog No. 153 free.

Sharples Co., Chicago, Ills. P. M. Sharples, West Chester, Pa.

Cow Sense

The editor has just received a catalogue, illustrative and descriptive of the

New Improved EMPIRE Cream Separator.

The author of this book refers to it as "A Treatise on the Application of Cow Sense to the Conduct of the Dairy," which very briefly yet expressively describes it. This catalogue is a departure from the general rule. It contains a fund of information and "Common Sense" suggestions which cannot help but prove of profit and interest to every owner of one or more cows. A copy is sent free upon request to

United States Butter Extractor Co., Bloomfield, N. J.

Western Offices, Fisher Building, Chicago, Ills.

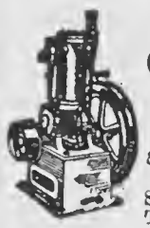
ROUND SILO

THE PHILADELPHIA.

The only perfect continuous open-front Silo made. See Open-Top Patent Roof. Ask for catalogue. E. F. SCHLICHTER, 321 Vine Street, Philadelphia, Pa.

Also made in the West by DUPLEX MFG. CO., South Superior, Wis.

CHARTER Gasoline Engine



USED Any Place By Any One For Any Purpose

Stationaries, Portables, Engines and Pumps, Hoisters

Send for Illustrated Catalogue and Testimonials. State your Power Needs.

Charter Gas Engine Co., Box 26, Sterling, Ill.

THE CHAIN-HANGING Cattle Stanchion

The most practical and humane Fastener ever invented. Gives perfect freedom of the head. Illustrated Circular and Price free on application. Manufactured by O. H. ROBERTSON, Forestville, Conn.

Wilder's Stanchion —being an improvement over Smith's. Lightest, strongest, quickest, safest swing stanchion made. Has steel latch and automatic lock. Becomes stationary when open. Animal cannot turn it in backing out. Made of best seasoned hard wood. Pins for fastening with every stanchion. Send for testimonials.

J. K. WILDER & SONS, Box 20 Monroe, Mich.

BOTH THEORY AND PRACTICE PROVE

The Superiority of the United States Separator

In Theory Its One-Piece Frame, Enclosed Gears Running in Oil, Few Parts, Three-Separators-in-One Bowl, and Superior Construction in general make it the

CLEANEST SKIMMING, MOST SUBSTANTIAL, SAFEST, EASIEST OPERATED, and MOST DURABLE Separator made.

In Practice It is daily proving the correctness of our theory, as testified to by pleased users all over the country.

If interested write for illustrated catalogues containing hundreds of letters to this effect.

BUY DIRECT FROM FACTORY, BEST MIXED PAINTS

At **WHOLESALE PRICES**, Delivered **FREE** For Houses, Barns, Roofs, all colors, and **SAVE** Dealers profits. In use **58 years.** Officially Endorsed by the Grange. Low prices will surprise you. Write for Samples. O. W. INGERSOLL, 246 Plymouth St., Brooklyn, N. Y.

BOMOJA COFFEE — BEST GROWN

New and Extra Inducements

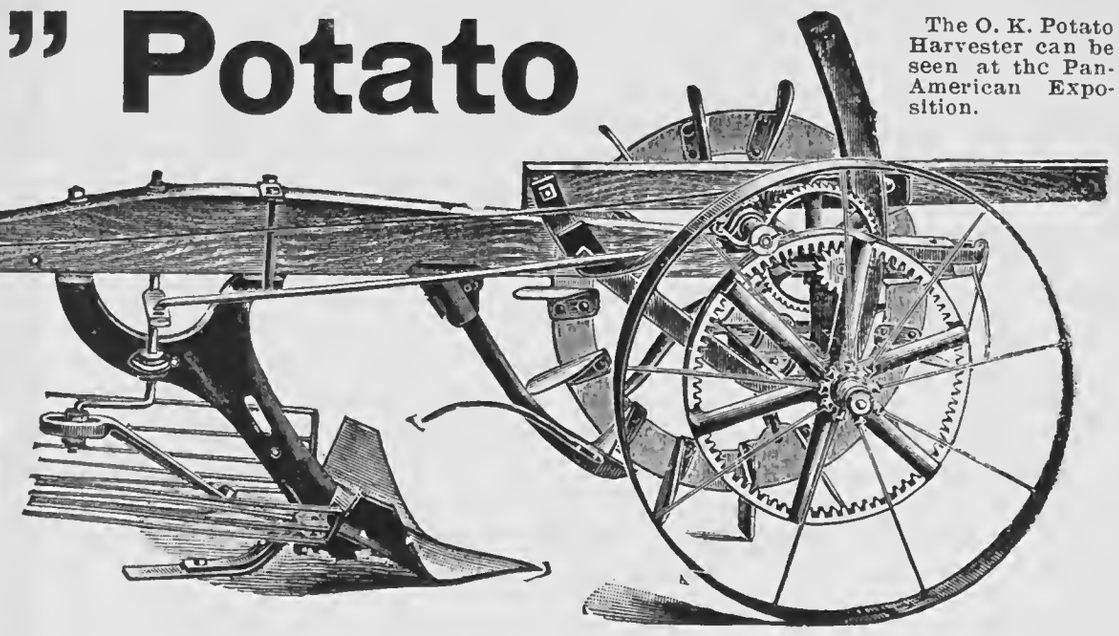
to sell our celebrated Teas, Coffees, Spices, Extracts and Baking Powder. 20 and 25 per cent to agents. Freight paid. For special terms address THE GREAT AMERICAN TEA COMPANY, 31 & 33 Vesey St., New York. P. O. Box 289.

BALES 15 Tons a Day HAY

The Gem Full-Circle Baler, lightest, strongest, cheapest baler. Made of wrought steel. Operated by 1 or 2 horses. Bales 10 to 15 tons a day. Sold on 5 days trial. Catalogue free. Address GEO. ERTEL CO., Quincy, Ill.

"O.K." Potato DIGGER

(*Patent Applied for.*)



The O. K. Potato Harvester can be seen at the Pan-American Exposition.

Guaranteed to do as good work in the same field as any four-horse elevator digger on the market, price one-half, draft one-half, cost per year for repairs one-fifth. Guaranteed to dig as clean as a man can with fork. Will make digging potatoes as easy, simple and inexpensive as cutting grass. Would such a digger please you? Will you buy such a digger?

We take all the risk; unsatisfactory work in your field means no sale. Every farmer who grows five acres or more of potatoes is interested. We wish to hear from all such.

D. Y. HALLOCK & SONS, Box D 805, York, Pa.
(Please mention box number.)

SAMSON GALVANIZED STEEL WINDMILL

No wind mill has ever met with such unqualified endorsement or sprung so quickly in popular favor. The cause is not far to seek. It is due to superior material and construction and the introduction of an entirely new and improved system. The **wonderful double gear**, adding double strength, double power, etc. The long bearings with interchangeable boxes which may be easily replaced without removing any part of the mill. Even distributed load. No overhanging strain or torsion. Stands the severest storms without bending or buckling. These are but a few of the leading features of the **Samson**. This is the last appearance of the Samson advertisement for this season. Do not fail therefore to send at once for our free **Samson Art Catalogue** and keep it for future reference.

Stover Mfg. Co., 502 River St., Freeport, Ills.

THE HOOVER POTATO DIGGER

A perfect machine containing improvements found in no other. Separates potatoes from vines and weeds. Rapid, clean worker.

Warranted. Dirt proof brass boxes, side hill spurs, special shovel, front and side levers.

Catalog free.

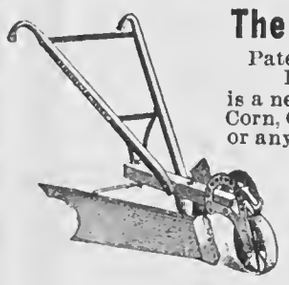
The Efficient Hiller.



Patented Jan. 30, 1900, U. S., Feb. 5, 1901, Canada, is a new implement for hilling Corn, Cotton, Potatoes, Tobacco or any kind of plant cultivated in rows. It can be adjusted in width to plant rows from 20 up to 40 inches apart. The peculiar formation of moldboards with extensions insures the banking of the soil close to and over the roots of plants at each side of furrow. The extensions brush the soil downward and outward, forming a uniform-shaped hill. The amount of soil desired over the roots is regulated by adjusting the wheel.

It need be drawn but once through between the rows, the earth having been previously cultivated. It is a labor-saving implement, and insures a good crop by protecting the roots of plants from heat and drying winds. Manufactured and sold by
VAN ALLEN WHITBECK, Aquetuck, N. Y.
Price $5. delivered at Ravena, West Shore R. R., Freight or Express Office, or Coyemans Landing.

BENEFITS OF THE CENTRALIZED SCHOOL.

CHILDREN CARRIED TO THE TOWN CENTER.

How It Works in Ohio.

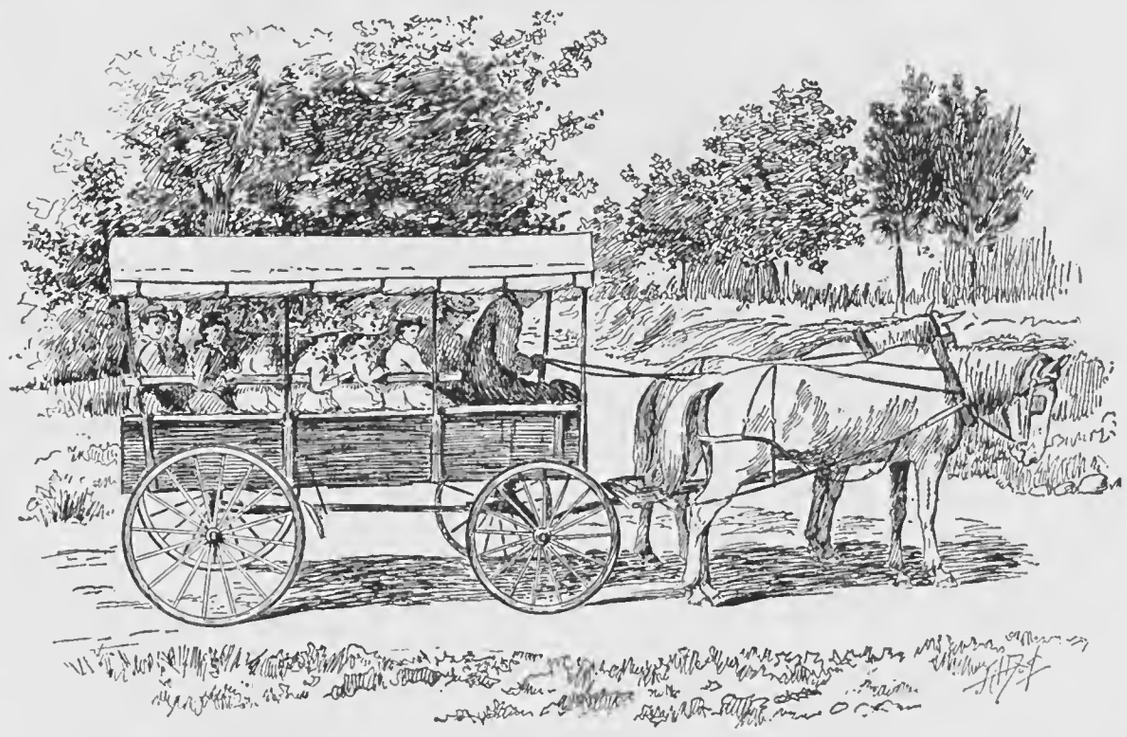
It was an early Spring morning. A cold, misty rain was falling, interspersed with snow squalls; the wind was strong from the northwest; under foot, the mud and water were having a "spat" for supremacy, and all nature seemed to be having a spell of "outs." Yet in the midst of it came the school wagonette drawn by a span of stout horses; while inside, protected from storm, wind, and mud, were 19 children bound schoolward, and all singing "Coming Thro' the Rye"; two youngsters were added to the load, the boot was again buckled up, and the song went on as the happy, dry little company finished their trip of a mile to the centralized school. When they had passed out of sight, I recalled reading last night an address delivered by a man who spoke of "hauling down the flag from the little red schoolhouse," of "children carted to school like calves, and pigs," of "children in a wagonette, and in the big schools, losing their individuality," of "increased expense," of "thousands of teachers being thrown out of work?" of "poor children being unable to attend schools because of poor clothing as compared with that of the village children," and lastly, "centralized children never came back to the land." All this in opposition to the plan of centralized schools. What are the facts in practice? Our township has had centralized schools on trial, and as a permanency now for over five years, and none of the things alleged above has been detected, and we believe never will be in a well-conducted system of rural schools. The idea of "taking down the flag," etc., is all sentiment. The flag waves just as protectingly over our centralized schoolhouse, the flags and emblems in the school rooms are as educational, and the patriotic songs sung by the children have the same inspiring ring, only deepened in volume, that they did in the little red schoolhouse. As to the children losing their individuality more by being taken to school in a warm, comfortable wagon, with order and decorum maintained—if needs be—than by children in groups tramping through mud, snow, cold and storm, as well as sunshine, to a school often 1½ to two miles away, it is hard to see. So far as good clothes are in evidence, the centralized school recognizes merit and proficiency for promotion, rather than clothes, and it is a fact that in this school referred to, it is the children of the poorer class of parents who stand, as a rule, in the highest lines of promotion for attainment and intelligence. I know that calico dresses and patched pants, if coupled with cleanliness and good behavior, work no detriment to any scholar. The idea that children are "carted to school like calves" is only to invoke the retort whether it is not as applicable to the children that parents send on foot through all kinds of weather to the rural school, where often the comforts and "conveniences" are as primitive as about an Indian tepee.

As to the centralized children not coming back to the farm, it is on trial, but they are as likely to remain in the country, as they would be to return to it after an education acquired in city or some educational center away from the influences of country life. Where the education of mind and hand goes together, as it does in the country in centralized education, and the education grows apace with the participation in farm work, and rural life, and its independence of shop rules, and freedom from dependence upon the turns of the labor market, we think the land will claim its full share of the centralized education. To my mind one of the greatest benefits of the centralized school, is in abolishing the clanship incident to the division of the rural schools; each neighborhood thus becomes a clan, with but little interest in community at large, and the matters of acquaintance of children in different parts of a town are slight. Often the pupils of the school at the center of the town—for there is, nine times out of ten, an embryo village in each town center in Ohio—are regarded by the rest of the children of the town at large, as of quite another race, and appointing themselves aristocratic prerogatives, which the brief association for an hour in the Sunday school does not wholly eliminate. Now all children of the town are of our community, and merit wins, not the parental possession of dollars, or being a factor in some "sphere of influence." One scholar is as good as another, and talent and deportment are the only avenues to merit, and in our school, the scholar from the back district is as often recognized as those to the "manor born."

It is not here contended that the centralized school is as yet perfect. It is in a state of evolution, but each step seems the better move towards solving the question of a better education for the rural boy and girl. In average attendance, the new plan far exceeds the old. In some towns the attendance is 25 per cent better on the average. It is fully that in our township. Then it promises to add at least two years more schooling to the school life of the pupil. To be taught along ever unfolding and new lines in study inspires, where the ever going back to retraverse old study byways, causes listless and lifeless ways, even to desertion of school life. The cost is less in most instances. The transportation of a school district to a central point is less than the cost of its separate maintenance. In some towns the centralized plan saves hundreds of dollars. In some the cost is about the same. In a few, where causes have been beyond the board's control, the cost is more, but in all cases, the instruction vastly compensates for the slightly increased cost. Granted that the cost is the same as by old methods, the ease and comfort in attending school, the increased attendance, the system of study and promotion, the increase in total months of school life, the actual participation in what actually amounts to manual training, rural education and life together, is not the centralized school a plan and a possibility worth striving to attain for the country, making rural life more worth the living? Shall this car of educational progress be helped forward, or its movement hindered?

JOHN GOULD.

Portage Co., O.



CHILDREN CARRIED TO AN OHIO CENTRALIZED SCHOOL. FIG. 147.

CORN-GROWING IN THE CENTRAL WEST.

Thick Planting for Shredded Fodder.

PART II.

SEED AND PLANTING.—It is not enough for seed corn to grow. It will often grow when its vitality is quite weak. Investigation shows that the crop is lessened more than commonly thought by lack of vitality in seed that grows fairly well. Experiments in peas where large and small sizes are planted show remarkable advantage in size alone. The greater abundance of starch stored in the seed gives the tiny plant a rapid, vigorous growth that is an advantage over weeds and weather that it never loses. In selecting seed corn how seldom one pays attention to size of grain, or to large vitality! With weak vitality corn will often start, especially if the weather is favorable, and if cold, damp weather comes, insects will destroy it and the soft grain sour. Nature covers the ear with shucks, and beds the germ in a cob with a layer of silk between the grains as high as the germ. Man ruthlessly strips off all protection and cords the ears on a brace in the barn, subject to every change of temperature and moisture.

VITALITY OF SEED.—A seedsman once said to me that he did not keep a fire in his corn crib in cold weather, but in muggy weather; that the moisture that is deposited on a rock will be absorbed by seeds, and that a sudden cold snap following such dampness is sure to injure the vitality of seed. On this account he keeps a fire in his crib in warm, damp weather to keep his corn dry, instead of in cold weather to keep corn warm. I have written far and near to learn definitely of the effect of cold on the vitality of seed corn, but from stations I have failed to learn of any experiments to test this effect of cold. This is passing strange to me, since the corn plant has been studied from every other standpoint. One station replied that it was so well-known that moisture and cold injured seed, that it was not thought worth while to test it. Another said that corn kept in cribs with no shuck on would not absorb moisture enough to weaken its vitality. They had not experimented any at all, and I do not know how they obtained information. It is decidedly contrary to experience. One experimenter said that he thought its vitality was damaged more by fungus attacks than by subjection to cold and dampness.

CARE OF SEED CORN.—This whole subject of care of seed corn has been woefully neglected. It is claimed that farmers lose 10 per cent of the oat crop each year from smut, and that often this is hidden in the plant, so as to not attract attention. Who is prepared to say that farmers do not lose 10 per cent or more in an average of 10 years by reduced vitality of seed corn by exposure? My own estimate is that the only safe way to keep seed corn is to get it air-dry before cold weather, and then never let it be exposed to a freezing temperature. I once bought some seed kept in a dry cellar. It was against the ceiling, and yet it was very tight on the cob. The bottom of the cellar was dusty, but there is danger of fungus growth and damage to vitality. This grew very well, however. I have dwelt much on vitality, because so recklessly neglected. It is of far more value than the question of selecting from ears near the butt or top of stalks or even the general shape of the ear or grain. A typical ear should be not less than eight inches long for central Indiana. The diameter should be one-quarter the length. I like the grains to be so built as not to leave a groove between their rows, and also like them to be wide and flat, instead of roundish

or rat-tooth like. One reason is that a flat grain has a larger germ; another is that it drills better. This is one reason why I shell off the tips and butts. The grains are inferior in shape and size. They drill badly, and I have more faith in a good grain and germ rightly drilled than in the late supply of pollen afforded by the tip grains. Corn drills much better if fanned, on account of removing scales and dirt that will sometimes run the grain over and make a skip. If seed is carefully selected, and the drill brush is in good repair the machine ought to drop even enough so as to not require thinning.

PLANTING.—In the Central West we are shredding so much fodder that we do not care for an earless stalk now and then. In fact, we plant twice as thick for the silo as we used to, and for shredding we plant thicker, and never care to thin. Sometimes we plant twice as thick for shredding. Some that feed out fodder with corn on, without shredding, plant thick so that there will be more ears with the same amount of corn, and smaller ears, so that the cattle can eat fodder and corn without crushing. Where our corn is planted 16 inches apart, one grain in a place, and rows 44 inches apart, the ears are so large and hard that we have to use a splitter or crusher to get a steer to eat enough to fatten. The drillers and hillers are about equal in numbers in central Indiana. This depends largely on the kind of land. If land is wet it is best not to put seed in a furrow. Some claim that if it is foul it is more easily kept clean in hills. The writer prefers drilling even in foul land. The stalks are single, and letting the fenders drag one can lap the earth around a stalk better than around two or three. We have a double drill that we like very much. It does its own furrowing, and drills two rows at a time. Many make a mistake planting corn deep in order to keep the roots down away from the plow. Corn is a grass, like wheat and Blue grass, and after coming to the top abandons the first root and makes a new root system near the top. It may surprise some to know that the roots of corn are no deeper under ground after it is a foot high, if planted four inches deep, than if planted one inch deep. The way to get the roots down is to plant in a furrow. The stalk comes up and sets near the top, and after once setting it will not change again if soil is thrown to it. The bottom of the furrow being two or three inches below the top the roots run off that low or lower.

I have tried both ways of planting, and am sure that the cultivator tears roots off much worse when planted without a furrow. Then, too, it is necessary in lapping dirt around the stalk to have a furrow. That is one reason I object to hilling. But with our late tools one may plant in a furrow and hill. As to depth of planting; Nature plants seeds two to four times as deep as the seed is thick, and corn will do well planted that way if it could be covered with a mulch, to prevent drying out, as Nature does. Practically, I like to plant corn as shallow as possible and not have it dry out in the hill before growing. The plant depends entirely on the starch in the seed to make its growth to the air, and if it is too deep it may exhaust that starch and come up spindling, or curl up in the ground.

Central Indiana.

THE HEN AS A MACHINE.

What She Needs in Her Food.

PART I.

In order thoroughly to understand this subject, let us begin at the bottom, or at least as near the bottom as present knowledge will permit us. First, let us quote from THE R. N.-Y. of August 28, 1897:

The realm of matter is composed of about 70 primary or chemical elements. By a primary element, we mean an element which cannot be subdivided by any known process of chemistry. Of these 70 elements, about 14 go to make up the vegetable and animal kingdoms. A subtle principle, which we call life, is present in every fruitful seed, fertile egg and embryo animal, which, if given the proper conditions, will gather to itself enough of these 14 elements of matter, and combine them in such a way as to form a complete specimen of its kind, and, taking the male and the female together, to perpetuate its species. In the case of the fertile egg, the first condition to be supplied is heat. Supply the proper degree of heat, and the life principle within the egg begins to gather to itself the elements of matter which Nature has placed within the shell of the egg. At the end of about 20 days, we have a chick with sufficient strength to burst its prison walls and come forth to the battle of life. Its next requirement is oxygen. As soon as respiration begins, it must have oxygen to unite with the carbon in its system, and keep up the fire of life begun in weakness. It can get part of the heat necessary to sustain life in this way, but it must flee often to the shelter of its mother's wing for additional warmth. As it increases in size and strength, it depends less and less upon the heat from its mother's body, till, at about six weeks of age, it can "go it alone" if it has proper shelter from storm and cold.

Its next requirement is food and drink. These must contain the same 14 elements of matter which it found within its shell. Nine of these are needed in very small quantities, and are supposed to be present in sufficient quantity in all ordinary food, viz: Sulphur, chlorine, iron, silicon, potassium, sodium, magnesium, manganese and phosphorus. The remaining five are oxygen, hydrogen, calcium, nitrogen and carbon. Of these, the chick can get a supply of oxygen and hydrogen from fresh pure air and water, so we need not worry about supplying them in the food. We now have the food question narrowed down to the three elements, carbon, nitrogen and calcium. The chick seems to have the power of securing a supply of the latter from crushed oyster shells and bones, so, if we keep a supply of these constantly in reach, we need not worry about supplying it in the food. We now have the food supply narrowed down to the two elements, nitrogen and carbon. If we supply these two elements in the food in digestible form, and in the right proportions, the vital functions can go on to best advantage, and the development of the chick will be normal and healthy.

If we furnish an insufficient supply of any of the elements needed, development will be checked. If we give an excess of carbon in the food, the chick has the power of storing up some of it for a future time of need, in the form of surplus fat; but this is not a normal condition, and the extra fat is in the way. I know no natural provision for storing up surplus nitrogen, but believe it quickly clogs up the system, poisons the blood, and is responsible for many of the ills of life, whether of chick or child. As soon as the pullet is sufficiently developed, part of the matter in the food is used to produce an egg in the effort of life to perpetuate its species. If she have comfortable shelter, and a well-balanced ration of food, with pure air and water, and crushed bones and oyster shells ad libitum she will lay all the eggs of which her individuality is capable. If her ration is not well balanced, or if any of the other requirements are wanting, she cannot do her best.

To illustrate: The Deacon has plenty of maple trees, and a good evaporating pan. His man, Mike, knows how to use it, and can make 50 pounds of sugar a day with it. If the Deacon set Mike to making sugar in the morning, what are his chief requirements? Sap to keep the pan filled, and wood to keep the fire burning. If the Deacon furnishes him with only half enough wood, or half enough sap, to make 50 pounds of sugar, Mike can go out and gather more wood or more sap as the case may be, just

BLACK TARTARIAN CHERRY TREE IN CALIFORNIA. FIG. 148

so the hen at liberty goes out and secures what we fail to furnish her in her food. Now, let the Deacon lock Mike in the sugar house with the evaporating pan, and we have a good illustration of a hen shut up in a pen, or in Winter when the earth is covered with ice and snow. Unless the Deacon passes in the sap, wood, and other requirements, in the right quantity and proper proportions, Mike cannot pass out his 50 pounds of sugar at night. Remember that the sugar house is small, and has storage room for only enough wood and sap to last a few hours at a time. If the Deacon keeps on bringing wood when Mike needs sap, his sugar is likely to scorch. He may pile up a little of the extra wood, but it will only be in his way, like the surplus fat on the hen's body. If the Deacon keeps on bringing sap when Mike needs wood, the pan will soon run over and quench his fire completely. If, however, the Deacon keeps on bringing the wood and the sap in just the right proportions, and in abundance, Mike can make his 50 pounds of sugar a day just as easily as if the door were not locked. If corn contains an excess of carbon for a hen's regular needs, then it is poor policy to give a hen a full meal of corn at any time, as some of her functions must wait for nitrogen, while the corn is being disposed of. If wheat bran or lean meat contains an excess of nitrogen for her regular needs, then it is poor policy to give a hen a full meal of wheat bran or of lean meat, as the case may be, at any time, for similar reasons.

The above was written more than three years ago. After three years of additional study and experience, I can find but little occasion to criticise it. I will, however, draw my pencil through the sentence where I said "Nine of these elements are needed in very small amounts, and are supposed to be present in all ordinary food in sufficient quantity," etc. While this is the popular belief, even among the best-informed scientific men, and may be true in feeding a cow or a horse, which consumes food for three or four years in order to build up the framework or skeleton of its body, my hens tell me that it is not true in their case, where this framework must be built up from the food consumed in five or six months. Some of these elements, besides the calcium, are undoubtedly secured from the crushed bones, particularly the sulphur and phosphorus. There are others, however, about which I am not so sure. Besides the 14 elements which the chemist can name, there may be others, as yet unknown even to the modern chemist.

O. W. MAPES.

SUGAR FROM SORGHUM AGAIN.

About 20 years ago considerable interest was aroused in the production of sugar from sorghum. Several factories were established, and quite a little money was spent by the Government in experimenting. It was finally decided that the beet and sugar cane were more profitable plants for the production of sugar, and, if we are not mistaken, the last factory in Kansas was abandoned several years ago. The great success of Germany and France in cultivating the sugar beet has changed the whole history of sugar making. A century ago the sugar islands in the South Atlantic were more valuable to their owners than gold mines, as they held a practical monopoly of the sugar production. When Napoleon began to encourage the cultivation of the sugar beet, without knowing it, he struck what has proved the death blow of these sugar islands. It has been argued of late years that the beet is to provide a large proportion of the sugar of the future, both in this country and Europe. Strange to say, we are again hearing from sorghum. Bulletin No. 51, from the Delaware Experiment Station, at Newark, contains some statements by Prof. A. T. Neale, which seem remarkable in the light of past experience. He states that the tropical cane of Hawaii surpasses all rivals, with a record of 10,400 pounds of supar per acre, as the average of 30,000 acres. As sugar cane requires 18 months to mature, the planting and milling of this would require the use of the land for two years. Hence, the actual annual yield of sugar per acre was 5,200 pounds. In Louisiana the best plantations have reached 4,500 pounds, but the average for the State is 3,000 pounds of sugar per acre. The beet in Germany is said to average 3,510 pounds per acre. In 1897 the average from the beet in this country was 2,700 pounds, although in California under the best conditions, 4,800 pounds of sugar have been made from an acre of beets. With these figures in mind, experiments have been made for the past few years in Delaware to see what could be done with what is known as "pedigreed" sorghum, that is, sorghum selected year after year from seed taken from the best plants. In 1898 the average crop was 2,717 pounds per acre, while the best acre reached 3,371. In 1899 the poorest yield was 3,500 pounds, and the most productive 4,700. In 1900 only one crop was made by the Station. For the month of October the average was 4,420 pounds per acre, one test during this period indicating 6,600 pounds. These figures, while, of course, on a small scale, indicate that "pedigreed" sorghum in Delaware can be made to yield as much sugar per acre as the average in Hawaii, and more than from the German beet farms. Prof. Neale, in speaking of the labor question, says that the Hawaiian planter has serious labor troubles to solve. He is experimenting with laborers from various countries; land is very expensive, and much capital is required for irrigation. In Delaware land is cheap and the labor question is simple, as the laborers are already on hand. At four cents per pound for raw sugar, one ton of sorghum, carrying 250 pounds of sugar, would be worth $10. A crop of 20 tons per acre is not unusual. During the past few years, experience with the silo has taught farmers how to grow corn and similar crops in large quantities. They can produce it for $3 per ton, and, if the figures are correct regarding the amount of sugar, there ought to be a good profit in the business. Prof. Neale goes into many details regarding the business of growing cane and making sugar. It must be said that he makes a good case at least from the scientific aspect of the matter. If it is possible to turn a large share of the Delaware peninsula into a sugar field the results will certainly be most gratifying to the farmers of that section of the country.

A FARMER'S STOCK.—I have a farm of 110 acres, well elevated. I am branching out largely in fruit. I have 10 acres of young apple orchard set 12 years, and fruiting finely; 10 acres or 250 trees set last Fall; 1,200 peach trees in their prime, and 700 Japan plums. I have seven cows, 10 sheep, four horses and 20 hogs, old and young; am quite largely interested in poultry. I have 225 pure Brown Leghorn hens; am going to add to my flock the Black Minorca this season. T. C.

La Grangeville, N. Y.

POTATO NOTES.—A correspondent from Oregon, in a recent issue of THE R. N.-Y., stated that he got most of his potato seed-balls in the shade. This concurs with my experience. I find that to get potato seed-balls, even in ball-bearing varieties, they must be planted in the shade. Two years ago I planted Carman No. 1 east of a piece of woodland, where the shade was on them most of the afternoon, and nearly all of the balls were in this shade. I have now some promising seedlings from this seed. I find that white potatoes are more easily affected with Potato rot, especially the stem end, than the pink and cream-colored varieties. Why is this? On this account I have to discard such varieties as the Carman No. 3, Rural New Yorker type, and plant Uncle Sam and the Rose class. If I could find a remedy for this stem-end rot I would still plant them, as they are good yielders, good shape and color and very smooth.

New Bellsville, Ind. C. W. F.

KILLING CANKER WORMS IN CALIFORNIA.

Experience With Paris-Green

We had thought that we knew all about canker worms, but our recent experience has proved that we did not. Last Fall we were sure that the regulation 16-mesh moth traps, properly put on, would prevent the female moths from ascending the trees. Now we know that the traps are a delusion and a snare, not to the moths but to us. We had 200 acres of fruit trees properly fitted with moth traps, and carefully examined in November to see that they were in place, and no holes where a moth could squeeze through, but in spite of our care we found eggs in the trees, saw the moths lay them, and have just finished the battle with more worms than we had last year. We now know better than to pin our faith to moth traps. To kill the worms before they ruined the trees we used shovels and poles and molasses and tar principally, but have experimented with spraying with Paris-green, and proven that the regulation dose of one pound of green to 200 gallons of water will not make *our* worms sick perceptibly. After trying a number of mixtures or ways of mixing the Paris-green we have found that three pounds of green to 200 gallons will stop them from eating, and they soon die. This is rank heresy from the standpoint of the experiment stations, and should burn the leaves disastrously. We have used some lime with the green part of the time but can see no difference when it is left out. The Paris-green that we use is supposed to be pure, but we have used three brands and see no difference in results. We are using Paris-green in the same proportion on apple trees for Codling moth.

April 29 we had finished our fight with the canker worms, and now believe that spraying is the most effectual as well as the cheapest way to dispose of them. The three different brands of Paris-green we used, each one said to be pure, varied in price from 22½ cents to 35 cents per pound. We are sure of one thing, and that is, that the usual recipe of one pound to 200 gallons of water is a useless mixture for canker worms. After experimenting we finally settled on three pounds to 200 gallons as sufficiently strong to kill the worms, and so sprayed all the prune trees at that strength, and also gave the apple and pear trees their first dose without changing the mixture. The addition of lime seemed to make no difference, for when put on without any lime no leaves were burnt. If canker worms come again next year we shall try to spray the entire orchard as quickly as possible after they begin to hatch, and then a second time immediately, as it will take a week or 10 days to spray 200 acres of trees. We have proven to our satisfaction that the ordinary 16-mesh wire moth trap will not keep down enough moths to make any marked difference in the crop of worms. A neighbor, however, seemed to be successful by putting printer's ink on the traps. The ink, by filling the meshes of the trap and some of it running through, remained moist on the under side, and thus caught all moths that touched it. I will say that in spraying almost any good force pump with a fair-sized air chamber may be rigged up for use, although the regular spray pumps are somewhat better in that the extra-large air chamber permits the man who pumps to attend to driving and keeping the mixture well stirred without reducing the force of the spray.

At Fig. 148 is shown the trunk of a Black Tartarian cherry tree; it shows how many of our fruit trees are allowed to grow. We find with most fruit trees that it is better to allow the branches to begin near the ground. From one to two feet of trunk is ample for most trees. Branches coming out so near the ground spread more gradually and make a strong support for a large top without being in the way of the horses while cultivating the orchard. The first orchard that I had to work in contained a lot of apple trees with heads from four to six feet from the ground, which resulted in a tendency of the branches to grow out horizontally, and getting lower each year at the ends, they soon had to be cut off. This cherry tree is our largest tree. It spreads over 30 feet and is probably 35 feet high. It bears large crops of fine cherries.

California. H. G. KEESLING.

AN ORCHARD SCHEME.—Regarding the distance apart for apple trees, I have a pet plan that I would like to see tested, which is based upon the sun's daily course. Wide apart rows north and south, say 50 feet apart, would allow the sun both early and late access. Then the trees could be closer than usual in the rows, perhaps 20 feet for large trees. At the time of day when the row shades itself, so to speak, the noonday sun is so high as to shine down into the trees. Certain advantages in this plan will suggest themselves. Has it ever been acted upon?

F. W. PROCTOR.

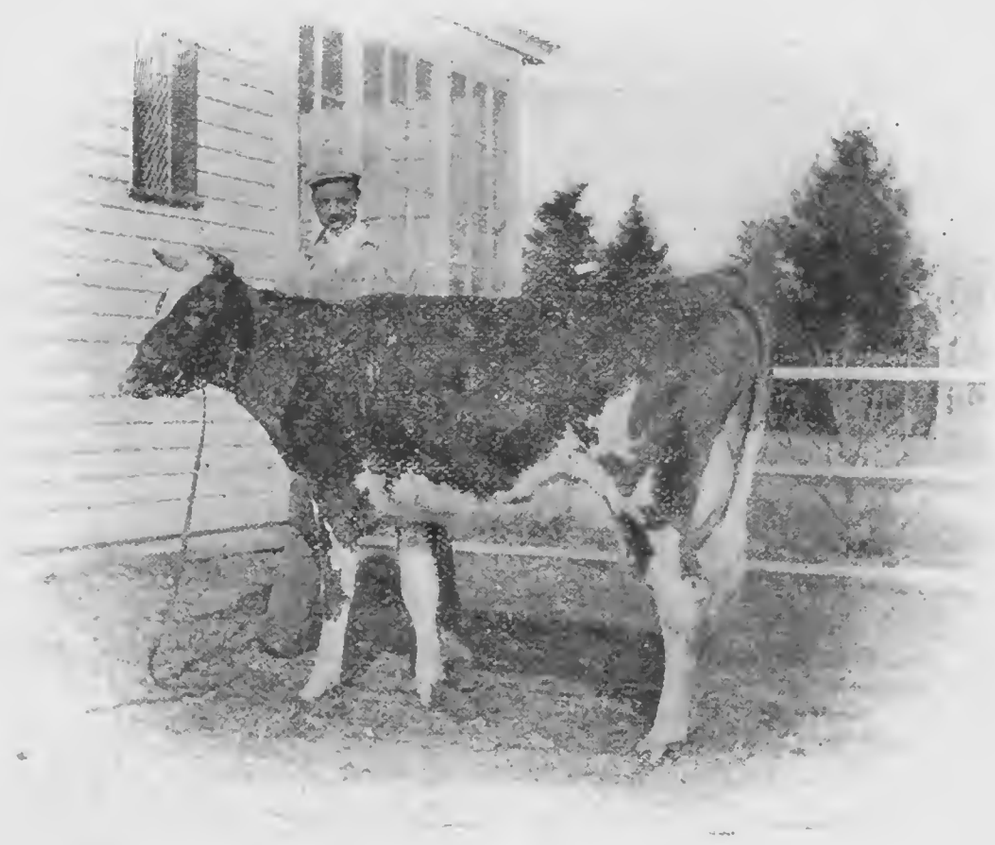
R. N.-Y.—Have readers ever tried it?

PARASITES OF TENT CATERPILLARS.

I had noticed the Forest tent-caterpillar for several years, but it did no particular damage till 1899. The Winter of 1899-1900 the trees were literally full of egg clusters which hatched, but just here, about the time when they should have been doing the most damage, they seemed to go crazy, and there was not one cocoon where in 1899 there were probably 50. In making examination of the cocoons I found some all right, some with a small white ant-like creature, which grew and became a waspish-looking fly nearly an inch in length as it came out of the pupa of the Forest worm. Others had a large maggot, some one to three small maggots. These emerged from the Forest worm pupæ, and went into pupa stage and then into a fly from size of house fly up. Others were filled with a large number of small maggots, but I think I got none of these in my collection. I never saw any of the waspish-looking creatures except those I hatched; I looked wherever I went, and there must have been a great many, as at least one-third of my collection of cocoons hatched such. The fly, which was about in equal numbers, was everywhere, especially around potatoes, and as the bug did not trouble (the slugs disappearing without doing damage), I surmised they were working on them. It is almost impossible to find a cluster of eggs on the trees now. R. J. R.

Springwater, N. Y.

The tent-caterpillars, both the apple and the forest or maple species, have many natural enemies, and were it not so, their ravages would continue until the maple sugar bush would be a thing of the past in many localities; for it is often impracticable to check the pest by artificial means in a forest, and man must there depend upon Nature's methods of reducing the numbers of the insect. Weather conditions, especially extremes or sudden changes, kill many of the caterpillars. The birds get many of them, and a bacterial disease sometimes sweeps them off by the thousands. Several kinds of predaceous insects eat the caterpillars, but more are destroyed by parasitic insects.



GUERNSEY COW AURICULA II., No. 12209. FIG. 149. SEE PAGE 383.

Among these parasites there are several kinds of flies, usually somewhat larger than a house fly. These flies stick their eggs on to the skin of a half or two-thirds grown caterpillar, and the maggots, which hatch therefrom work their way into the interior of their host, where they get their growth on the fats and juices which the poor caterpillar elaborates from the leaves it eats. As the maggots avoid eating the

ICHNEUMON FLY DEPOSITING EGGS IN COCOON. FIG. 150.

vital organs of their host, it grows and finally spins a cocoon about itself, but rarely is there enough left of the caterpillar to make up the moth into which it was destined to transform; so that there emerges from the cocoon one or more of these Tachina flies or parasites instead of a moth. Again, thousands of the caterpillars escape the jaws of their enemies and get into apparently safe quarters inside their silken cocoon, but alas, they are far from safe there. For there are two or three kinds of Ichneumon flies whose maggots find the caterpillar or pupa in the cocoon a dainty morsel. "It is very interesting to watch one of the Pimplas or Ichneumon flies when placing her eggs in the cocoons," says Perkins. "She is so intent upon her task that one has no difficulty in observing her closely. She is quite brisk even to nervousness in her movements, flying quickly from one cocoon to another, hastily, but sharply, inspecting each. If the caterpillar inside has not finished spinning and its last moult she does not leave an egg, but flies off to the next cocoon. If the cocoon is done and the pupa is formed, she then places herself over one end, and strongly arching the abdomen thrusts her ovipositor into the pupa. See this act in Fig. 150. Then by two or three successive thrusts she works the egg deeply into the unfortunate victim, withdraws the ovipositor and flies away. Sometimes she will examine and leave several cocoons before she finds one that she considers a fit place for an egg, but often the eggs are deposited rapidly. I have seen five cocoons thus parasitized in less than as many minutes. In rare instances both moth and parasite come from the same cocoon, both apparently well developed."

We confidently expect that these little enemies, together with climatic conditions and other natural checks, will soon get the upper hand, so to speak, and relegate the "Maple worm" into the background as a serious pest for many years to come. The "up" or destructive period with tent-caterpillars usually lasts several years, but their enemies also often keep them "down" for a longer period. If all were as observant of Nature's ways as R. J. R., how much more information and intellectual enjoyment could be got out of life. M. V. SLINGERLAND.

A WINDMILL SCARECROW.

The only effectual scarecrow I ever found is a windmill. I formerly made them to jingle a bell as they turned but later found that their motion alone is just as effective. I take two pieces of pine two inches square and about two feet long. These are first balanced on a knife-edge to get their center of gravity. Make a side mortise in each, cutting half through, tack them together at right angle, and we have the four arms. Bore a hole for the axis and insert an iron box, or else tack a washer on each side to prevent wear. The floats are the sides of quart tomato cans, unsoldered in the fire, rolled out flat and tacked to the arms, which have previously been beveled by taking off corresponding corners. Another strip of two-inch stuff about three feet long is required, a piece of tin or a shingle is tacked to one end for a vane, a hole is bored longitudinally in the other end to receive a bolt, which is then driven in with the wheel upon it. After being thus mounted the center of gravity is found, a hole bored through the stick at this point, and the whole mounted upon a stout pole set in the ground, using a bolt for a spindle to allow the vane to turn in the wind. Such a contrivance has never failed with me to prevent, or to interrupt the work of crows even where they have commenced their depredations. F. W. P.

A Vermont Apple Crop.

Prof. F. A. Waugh, of the Vermont Station, wrote to the Burlington Free Press an account of a profitable apple orchard owned by Mrs. Lura E. Allen, on South Hero Island in Lake Champlain. Last year this orchard of 14 acres gave a net profit of $100 per acre. This year the returns, according to Prof. Waugh, were as follows:

No barrels sold in New York	903
Gross receipts	$2,785.75
Average price by the barrel	3.08
Commission, freights, cartage, etc	521.61
Net cash returns	2,264.14
Additional fruit sold at home	300.00
Total cash returns	2,564.14
Average by the acre, 14 acres	183.08

No wonder Prof. Waugh asks which was the "off" year in this orchard! Right in the neighborhood of this orchard last Fall some apples were worth only 75 cents a barrel, but those sold by Mrs. Allen brought, in a few cases, as high as $6 and $7. Prof. Waugh well says: "Farming which pays $183 an acre, cash in the bank, is evidently successful; and Mrs. Allen ought to be publicly thanked for the benefit of her good example."

DRILLING CLOVER SEED.—I have been interested in the discussions of how to treat the grain fields in the Spring so as to insure a catch of grass. I have always sown the seed early, when the earth was cracked by the frost, but there has not been such a time this Spring, and then the rains came and the ground seemed to be so hard that I thought it useless to sow the seed. I felt afraid of the harrow; the weeder wouldn't touch the ground, but to-day I solved the problem. I was going to the field to sow oats with my Buckeye grain drill when it occurred to me that it would be just the thing to go over the wheat with it to loosen the ground, the hoes running just between the drills of grain and sowing the grass seed at the same time. I have tried it, and a more complete job you never saw. I don't think it pulls up one stool of wheat or a bit of young Timothy, the latter being mostly among the wheat in the drills.

Plainfield, N. J. W. H. P.

Van Deman's Fruit Notes.

ALL SORTS OF QUESTIONS ANSWERED.

Catawba Grape.

J. J. M., Monsey, N. Y.—I thought of setting out a few Catawba grapevines, but I do not see them listed in any of the catalogues I have. What is the matter with them? Will not Catawba grow in this section?

ANS.—The Catawba is a most excellent grape, and does very well in most sections when sprayed with Bordeaux Mixture to keep down mildew and black rot. The liability to these diseases is the principal objection to this grape, and this is probably the bottom cause of the scarcity of the plants in the nurseries.

Spraying Peaches for Rot.

G. S. E., Ennis, Tex.—Last season all of my late peaches—those ripening in September and October—rotted on the trees before ripening. Can you give me a remedy to prevent it in the future? I have already sprayed them three times this Spring with Bordeaux Mixture. They are now as large as the end of one's little finger.

ANS.—Bordeaux Mixture is the proper preventive to use for Peach rot, and if one or two more applications are used before the fruit is ready to color it is not likely that there will be any trouble from the same cause as last year, even if the climatic conditions are the same.

Winter Apples for Kentucky.

J. W. McD., Warsaw, Ky.—I wish to plant some Winter apples. What would you suggest as desirable for this section? Would Stayman do well here? I am located on the Ohio River bottom, between Louisville, Ky., and Cincinnati, O.

ANS.—In my opinion Stayman would be one of the best apples that could be planted in Kentucky. It is a seedling of Winesap, which has long been one of the most successful varieties for that region, and Stayman is giving promise of being even better. York Imperial is another good one. Both will succeed on the bottom lands mentioned, although they do somewhat better on uplands, where the soil is good.

Rabbits Attacking Young Trees.

M. E. S., Bendersville, Pa.—I have a young apple orchard of about 5,500 trees, about half of which I treated to a solution of whale-oil soap, (two pounds to the gallon of water). Since using the soap the rabbits have been working on them. Is there any application I can use that will stop their depredations and not injure the trees?

ANS.—I have tried a great many kinds of washes to prevent rabbits from gnawing the bark from apple and other trees, and all I know of that are really effective are also injurious. In some cases the milder and harmless ones were effective, except when the snow covered about all that the rabbits liked to eat except the trees, and then they would eat regardless of the coating over the bark. Wrapping is the only safe way that is sure.

Grafting Cherries.

E. M., Danbury, Conn.—In your issue of March 16 I notice article on grafting black cherries. You say "avoid splitting the central pith." I take it to be that you must not split through the center of the stock, but one side of it. Am I correct? I can graft almost anything successfully but cherries, which with me have been a total failure. I have never had any success in budding. Will you explain how it is done, how the buds should be prepared for insertion, and when is the best time to do it?

ANS.—I have noticed that some grafters advise splitting to one side of the center of the stock instead of through the center, but I have never noticed this to be an important point, for I have had very good success in both ways with the cherry as well as with other fruits. It is possible that one cause of the failure mentioned is that the grafting has not been done early enough. The best success seems to be with very early grafting, when there is not the slightest sign of the buds starting. Budding is done by cutting a slit in the bark of a young stock, such as one that is not larger than one's finger nor smaller than a lead pencil, and then making a cross cut at the top, and into this opening in the bark slip the bud. The bud is cut from a scion of the present year's growth, by taking a piece of bark about an inch long with the bud in the middle of it. I usually leave the little particle of wood attached to the bark that comes off with it. When slipped well into place the bark is tied firmly down upon the bud with some such bandage as raffia or strips of old muslin, or even cotton strings The inner corn shucks make very good bandages when they are long enough, by tearing them into strips about a half-inch wide. The best time to bud is in August or the early part of September.

Spraying for Codling Moth.

C. L. P., Boulder, Col.—Can you tell something of experiments in the West with spraying throughout the season for the Codling moth? I would like information as to practice and results.

ANS.—Codling moth is an abundant and serious pest all over the country, and seems to be worse in the Far Western than in the Eastern States. The dryness of the climate is supposed to be very favorable to its propagation, for there are at least three broods there each year. The remedy is thorough spraying with the arsenical mixtures. Paris-green is effective, but there are preparations of white arsenic that are both cheaper and more effective. One of them is made by boiling together for 15 minutes in one gallon of water one pound of white arsenic and two pounds of sal soda. One quart of this is sufficient for 50 gallons of water. It is necessary to add two pounds of lime to each 50 gallons of the poisoned water in case Bordeaux Mixture is not used instead of water, because of the caustic effect of the arsenic without the lime being added.

Apples for New York; Pasturing in Sprayed Orchard.

R. E. B., Pleasant Valley, N. Y.—1. What varieties of apples would be best to plant for a commercial orchard? I am situated about 80 miles from New York. How would the Baldwin, R. I. Greening, Rome Beauty and Northern Spy do, with Wagener for a filler? 2. Is it dangerous for cattle to eat hay from an orchard sprayed with Bordeaux and Paris-green? Would pigs running in a sprayed orchard be injured by eating grass?

ANS.—1. The first four varieties mentioned would be very good for the Hudson River Valley, and no better selection could be made for a filler than Wagener. This list can hardly be improved upon for that section. 2. No, there is no danger from all the poison that is likely to fall upon clover or grass in a sprayed orchard and afterwards eaten by cattle. This point has been tested at least once in Michigan by purposely feeding grass that was so sprayed to a horse, and with no bad results. Chemical analysis proved that it would require the poison on over 1,000 pounds of such grass to kill a horse or cow. Pigs would not be injured by eating grass in a sprayed orchard. They are not so easy to poison as cattle and horses.

Pears for Illinois.

H. M., Morton, Ill.—What six varieties of pears would you advise setting here? I would like two varieties of early pears, two for Fall use and two for Winter. The soil here is a deep black loam, and is not as well drained as it should be. All of the pears we ever set out died with the blight except Kieffer. Will too wet ground cause blight? What do you know of the Sudduth pear? Is it blight-proof as claimed? Has it been thoroughly tested yet? One nurseryman near here claims to control the sale of it, and he sells it for $2 per tree. I see the claim is made by a nurseryman here that the Lincoln pear and the Lincoln Coreless are two varieties, and that the Lincoln Coreless is a worthless variety. Is this true?

ANS.—It is presumed that the writer intends to plant pears for commercial purposes, and if so the list would be somewhat different from one for home use. Of the very early kinds, Wilder Early and Tyson are perhaps the best, although early pears of any kind are usually not very profitable. Bartlett is the most profitable of Fall pears, or for that matter of those of any season. Its main fault is liability to blight, but it is no worse than many kinds of less value in other respects. Sheldon is another excellent variety. Of the Winter kinds of good quality, Lawrence is the best, but there is perhaps more profit in Kieffer than in any other pear, although it is exceedingly poor in quality; except when ripened under certain peculiar conditions, when it is of fair quality. The Sudduth is a new variety that has been tested but little outside of Illinois. It is reported to be very productive at an early age, and that the tree is comparatively free from blight. The quality is only fair, and the appearance is not very attractive, being green in color and without a blush. The flesh is rather soft when it ripens, and I fear it would not be a good shipper. It may be well to try a tree or two of it, but it certainly would be unwise to plant of it more than for testing, until we know more about it, and I should not want to pay a big price for the trees even for that purpose. The Lincoln pear is a comparatively new variety and is only fair in quality and scarcely worthy of more than a trial; but the Lincoln Coreless, which is an entirely different pear, is absolutely worthless.

IN PAINTING barn or house it is well to remember that Pure White Lead never cracks or peels, but wears away very slowly and gradually, perfectly protecting the wood from decay so long as a vestige of the paint remains upon the surface.

In repainting a building, if Pure White Lead is used in the first instance, no dangerous gasolene paint burner is required to put the surface in good condition for a new coat.

The brands of Pure White Lead manufactured by the National Lead Company, named in margin, are made by the "*old Dutch process*" of slow corrosion and are the best White Lead that it is possible to manufacture.

For any color or shade required, use NATIONAL LEAD COMPANY'S Pure White Lead Tinting Colors. Pamphlet sent free upon application.

National Lead Co., 100 William Street, New York.

The Cornell Reading Course.

Edited by John Craig, Professor of University Extension, and Editor Farmers' Reading Course, Cornell University, Ithaca, N. Y.

A Quiz on Plant Physiology.

Your reading lessons have all been very interesting and instructive to me, and will bear much thought and study. The subject of film moisture was entirely new to me, and corrects many mistakes I was laboring under in regard to moisture in the soil. I readily understood how the soil water enters the roots of plants by the process known as osmosis. Is it this same process which forces the sap to the top of tall trees away above the limit of capillary attraction or atmospheric pressure? Given two equal plants, one in "poor" soil and the other in "rich" soil. Does not the plant in the poor soil have to absorb and transpire an excessive amount of water? Or, in other words, will not an abundant supply of water in the soil make up in a degree for a deficiency in plant food? B. H. C.

East Bloomfield, N. Y.

"Osmosis" is the principle which distributes the food throughout the tree, but it is not due to this cause that we have the phenomenon of sap pressure. Those who have practical acquaintance with sugaring operations know that after a sharp frost they may expect a good run of sap. In the maple, the pressure is downward, not upward, as in the case of the birch. There has been thus far no satisfactory explanation of this phenomenon of sap flow in Spring. One of the most reasonable theories is this: The action of the frost is to withdraw from the cells the water which they contain, and collect it in the air spaces or interspaces between the cells. The air is reduced in bulk by the fall in temperature, and the sap still further compresses it. On the return of higher temperature the water and the air expand. This brings about a general condition of tension, and this tension continues until the cells have reabsorbed through their walls this sap water which was withdrawn. Now while this explanation appears to be a plausible one of the pressure of sap in the maple, it does not explain the upward root pressure that is found in the birch. It was formerly held that osmosis did it all—but now investigators say "don't know."

I do not think that one plant in poor soil could equal the growth of another plant in rich soil simply by an extra supply of water. Undoubtedly the larger amount of water would enable the plant more thoroughly to utilize the elements of food which the soil contained, but it would not make up for the difference in quality or quantity which existed. A generous supply of water in a poor soil might keep a plant going for some time, but there would eventually come a period when more than water would be required. Neither a concentrated food on the one hand, nor a very dilute liquid ration on the other would be likely to produce a healthy organism. Plants take this food from the soil in the form of a soup, but it must not be too thin.

More Light Wanted.

1. I have seen a notice of the Cornell Reading Course, and wish I could know more about it. We have a large garden and wish to get the most out of it for family use. I would like to know about fertilizers. It is difficult to get good stable manure; the soil is loam. 2. We have two pear trees which are troubled with blight. Last year I dug the earth from the roots of one of them and sprinkled sulphur plentifully over them, covered; then I trimmed all the affected branches from the tree and dusted sulphur on the surface, and no other limbs were affected during the remainder of the Summer. 3. Will you give a treatment for lawn where creeping weeds have appeared? S. W. H.

Waverly, N. Y.

1. The Cornell Reading Course is a correspondence course in agriculture free to residents of New York State. Information and copies of the lessons of the first series of the Farmers' Reading Course are sent to all who deserve them. Lesson 3 gives information regarding the function and use of commercial fertilizers. If you study this carefully I think it will help you materially. 2. I do not think that such treatment as you have given your pear tree will in any way prevent the recurrence of blight. This is a disease which finds entrance, not through the roots, but through the partly-grown leaves and young shoots. It is caused by a germ which spreads in the sap of the tree. The only way to prevent is by practicing good sanitation. As soon as a diseased branch makes its appearance it should be cut off and destroyed. The pruner ought to be careful to cut well down into the healthy tissue, so that all the microbes which cause this disease are likely to be removed. Trees making a rank sappy growth are more susceptible than those growing slowly and ripening their wood thoroughly. 3. Lawns which are shaded by trees or are imperfectly drained are difficult to keep in a good grass sward. The only way to keep weeds out is first to destroy them as they make their appearance, and second to encourage the growth of grass by the application of fertilizers. It is a good plan to sprinkle the lawn two or three times during the season with a fertilizer containing some of each of the three principal elements of fertility—namely, nitrogen, phosphoric acid and potash. A light application, say 200 pounds per acre, should be made in early Spring, and other applications should follow at intervals during the Summer. Top-dressing with barnyard manure is objectionable.

Bleeding from Grapevines.

J. R. F., Belleville, Pa.—Does bleeding hurt grapevines, and why did they do so when I pruned them last Fall? I thought the cut would be healed sufficiently to shut off the sap, but it is not so in this case. Is it caused by very warm weather after a late cool Spring such as we have had?

ANS.—Bleeding, or the oozing of sap from cut vines and branches is not considered harmful, as probably no more sap is lost than would be supplied to the part cut away. Vines do not often bleed when pruned so early, as the cut surface should be well sealed by Spring. Probably the best time to prune grapevines is in late February or early March. The cut ends generally dry over, and the loss of sap should be very small. The cause of the excessive bleeding in your case seems to be quite obscure.

Temperature for Cool Grapery.

W. H. W., Malden, Mass.—What temperature should be maintained by day in a cold grapery?

ANS.—During the greater part of the growing season the cold grapery is kept at about the same temperature as outside by means of free ventilation. In pleasant weather the ventilators should remain open all night, but during cold storms they may be closed. As the season grows colder they should be closed sufficiently to maintain about 70 degrees when possible. Hot graperies, when first started, should have about 50 degrees at night and from 65 to 70 degrees during the day. In three or four weeks it may be raised to 60 degrees at night and 80 or more during the day. Ventilation should always be freely given on bright days, but the houses may be closed early in order to trap the sun heat and warm the houses for the night.

SCRAPS.

KANSAS FRUITS.—Among the best very early peaches are Triumph, Sneed and Greensboro. Of the late kinds Chairs, Fitzgerald and Heath Cling are excellent. Elberta is good for midsummer. There are two classes of plums that succeed in Kansas, the Japan and American. Of the former the following kinds are good: Abundance, Wickson, Burbank and Georgeson, and of the native kinds, Wild Goose, Milton, Hawkeye and Wyant are among the very best. There are so many good strawberries that it is difficult to name any one as the very best of all. Besides, the use for which a variety may be intended is an important point. I would suggest the planting of at least two kinds, whether their flowers are perfect or imperfect. Glen Mary, Warfield, Carrie and Gandy make a good list for family use.

H. E. V. D.

TASMANIA now raises 500,000 bushels of apples a year. The trees are set very closely, about 10 feet apart, it is said; large crops are raised, England now being the chief market outside of Australasia. Tasmania ships green fruit to Australia and New Zealand. It raises quantities of pears, plums, cherries, and within the past few years has been exporting about $150,000 worth of jam annually. This latitude gives the strawberries, raspberries, grapes and other small fruits an excellent flavor, and the Tasmanian jams go as far north as the Philippines.

OATS and Spring barley are all up nicely. Corn planting begins to-day in many fields. Nearly all breaking done. Early-sown wheat all gone; late-sown looks fine. The Hessian fly seems to be afflicted with parasitic enemies, and may cease its ravages. Pastures short and dry feed still shorter. Peaches in full bloom. Corn, 50 cents; wheat, 80 cents; oats, 33 cents; hay, $16 per ton; eggs, 12 cents; butter, 14 cents; potatoes, 60 cents; hens, eight cents; hogs, $5.25. Of sheep and cattle none is changing hands. Tobacco selling rapidly at seven to 10 cents per pounds. The river is all over bottom lands. C. D. L.

Brown Co., O.

Remember a fifty cent bottle of Scott's Emulsion given in proper quantities will last a baby fifty days; a child six or seven, thirty days; and a child of ten or twelve, twenty days.

It's a very economical medicine.

If the child is sickly, without appetite, it will nourish and bridge it over until it can take its usual food.

For delicate children without any real disease, it can be used with splendid results.

We'll send you a little to try, if you like.

SCOTT & BOWNE, 409 Pearl street, New York.

Farm Blacksmithing. An illustrated book written expressly for farmers. It tells all about making and tempering steel tools, making chains, hooks, rings, clevises, bolts, etc., etc. Filing saws, splicing rope, shoeing horses. Price 50c., cloth bound, by mail post-paid. Address J. M. DREW, St. Anthony Park, Minn.

BINDER TWINE

It affords us great pleasure to quote prices for our famous and well-known grades of binder twine as follows:

Pure White Sisal, 8c per lb. Standard, 8c per lb. Manila, 9¾c per lb.

These prices are for any quantity not less than a 50-pound bale, free on board cars Chicago, and are not subject to discount. TERMS:—Cash to accompany order.

The above twines are our unexcelled "SMYTH" BRAND, pronounced by all who have heretofore used them to be the best in the world. They are prepared with special care from first quality selected hemp, every ball being separately tested for evenness and tensile strength and insect prepared before being allowed to pass examination, hence it is absolutely perfect, is reputed the very best binder twine in the market and we believe it to be worth 2c per pound more than any other binder twine in the market.

WE GUARANTEE our customers against any change in our price and if we go lower, you will be refunded the difference in price. We treat all our customers alike and the early buyer is afforded as much protection as the late one.

SAMPLES FREE. We guarantee our twine, every pound of it, and we will refund your money instantly and without a question if it fails to come up to our representation either in quality or count, but if you prefer to see samples before ordering, then write to us and we will send samples by return mail so that you can see and test it.

JOHN M. SMYTH CO. 150-166 and 287-289 W. MADISON ST. CHICAGO, ILL.

Ruralisms

NOTES FROM THE RURAL GROUNDS

THE GIANT HARDY PRIMROSE.—This immense new primrose is now blooming on the Rural Grounds, the plant having lately been received from the American distributor, Henry A. Dreer, Philadelphia, Pa. The general appearance of the plant is very similar to Primula Polyantha except that it is much larger in all its parts, and of very robust growth. The flowers open as large as a silver dollar, and the trusses of bloom often exceed six inches in diameter. The color is a bright yellow with an orange center, and the characteristic fragrance of the European wild primrose is retained. It is thought to be a hybrid between P. vulgaris and P. Polyantha, as it first appeared among a batch of seedlings of the latter. As it now appears, it is safe to say that it is fully three times as large as any other hardy primrose. It is claimed to bloom earlier and keep at it longer than any other variety also, and to be especially desirable for forcing, as it is one of the easiest plants to bring into bloom under glass. They can be kept dormant until wanted and brought into flower in a cool greenhouse in about five weeks' time. Hardy primroses have never gained the popularity in this country they have always been favored with in Europe, but this giant variety will go far to arouse interest in a most desirable class of plants. They may be grown anywhere in moist, rich ground, but are chiefly suitable for borders and edgings on account of their trim and neat habit.

THE BARTLETT PLUM.—This very promising new plum, originated by Burbank, and sent out three years ago, is the neatest grower among plums on the Rural Grounds. A little "June-bud" tree received from Joseph H. Black, Son & Co., Hightstown, N. J., is, after a season's growth, the most symmetrical tree on the place. It grows upright, more like a pear than a plum, and the branches are arranged almost as evenly as a candelabra. The dark foliage is also very glossy, adding much to the ornamental effect. Mr. Burbank describes the plums as possessing the fragrance and flavor of the Bartlett pear in even a higher degree than that favorite variety. A sample received last Summer was of fair eating quality, but had evidently deteriorated during transportation. The color was yellow with a crimson flush, and the flesh salmon red, firm but juicy. The pit adheres slightly to the flesh.

WATER CRESS.—This appetizing relish is now abundantly supplied to most city markets. It is gathered up by large jobbers, and an unbroken supply comes to the North all Winter from southern streams. At one time the cultivation and harvesting of water cress from streams near the Summer resorts of Monmouth Co., N. J., was a considerable industry, but it fell into the hands of a combination which has since extended its operations to other fields. There was practically no indigenous water cress in the many little streams flowing to tide water in this region previous to 1896, when a quiet but observing individual, while spending his Summer vacation in the locality, conceived the idea of stocking such streams as appeared favorable to its growth. For several successive seasons he sowed seeds near the sources, and the result became apparent in such a vigorous growth of cress that the currents were often checked and the growth smothered in mud and sand. The interloping cress has generally died out from the streams where the channels are not preserved by digging or dredging, but it still persists where the conditions remain suitable. Few attempts at the naturalization of plants and animals where they have not previously existed are entirely successful, as some of the necessary conditions may be lacking, though supposed to be present. Very little cress is sent to the New York market by individual growers or shippers. Most of it now comes from West Virginia and is carefully graded and packed in ice, in large barrels. The day of large profits from a small natural or cultivated area in water cress is past.

THE LAGGARD SPRING.—During the prolonged gloom of our wet and stormy April we comforted ourselves with the thought that vegetation would advance so rapidly with the advent of warmer weather as to make up for lost time, but the hope is still unrealized. At this writing, May 10, peaches are still in bloom, pears and cherries just opening, and apples yet in small buds. Cold winds and drenching rains continue their retarding influence, and doubtless pollination has been unfavorably affected in the fruit blooms already open. A few days of warm sunshine would prove most acceptable. Even some of the cool-blooded bulbous plants appear to have had more cold moisture than they required. Tulips are large and brilliant, but hyacinths and daffodils are noticeably dull in color. The trusses of the former are large and full, as might be expected from their slow development, but brilliancy of color is lacking. Pansies are extremely large and handsome, as they find conditions just to their liking. W. V. F.

Melon Blight and Soda Bordeaux.

R. J. E., Berrien Co., Mich.—I have been much interested in the articles on Melon blight which have appeared lately in THE R. N.-Y. There are hundreds of acres of muskmelons raised in this vicinity for the Chicago and Milwaukee markets. The Osage originated here near Benton Harbor, and the business of growing melons for market has grown to be the chief occupation of a great many small farmers. Within the last few years leaf blight has made its appearance, and has gradually increased, until last year a great many crops were ruined. It usually makes its appearance about the time the melons begin to ripen and spreads rapidly until the field will look as though a fire had run through it. This causes the melons to ripen prematurely and spoils the flavor, so they are unfit to eat. I shall try the Bordeaux Mixture this season and hope it will prove effectual, though it seems to me there is one serious objection to its use. If used late after the melons are nearly grown, will not the lime form a white coating on the melons and make them unsalable? I have heard plum growers complain of such a condition where they had sprayed with Bordeaux after plums were partly grown. As I understand it lime is used simply to neutralize the acid in the sulphate of copper. If so, is there not some other alkali that will do this without the objectionable white color? How would sal soda do? How should it be used?

ANS.—We have used what is known as the soda-Bordeaux on potatoes. In this soda lye takes the place of most of the lime. The proportions are three pounds of sulphate of copper, one pound can of Lewis lye, five ounces of lime and 30 gallons of water. The copper is dissolved the same as in making the ordinary Bordeaux, and diluted so as to make 15 gallons. The can of lye is dissolved in two gallons of water and then diluted to five gallons. The lime is slaked in hot water and diluted to five gallons, after straining through a coarse cloth. The 15 gallons of copper, the five gallons of lime and the five gallons of soda are then mixed, with water enough added to make 30 gallons. In our experience this has given as good results as the lime Bordeaux. It sprays easier, does not scald as badly, but does not stick to the vines as well. Mr. F. A. Sirrine, who gave the information to Holmes Bros., says:

"We have always prepared Bordeaux Mixture for pickle and melon spraying with the yellow prussiate of potash test, and in this way have never had an excess of lime to discolor the fruit. In fact, where the vines are vigorous, only a small portion of the mixture strikes the fruit, and there is no danger of scalding the fruit with the mixture. Of course some of the mixture may show on the fruit, and when a man is growing for market purposes he should avoid anything that will excite suspicion in the appearances of his melons. Although I have not tested the soda-Bordeaux Mixture I think it would be well to advise the use of the ordinary Bordeaux Mixture until the melons become so large that the leaves do not protect them, after which he can use the soda-Bordeaux Mixture."

Starving or Feeding Pears.

W. E. G., Hammonton, N. J.—When I came here in the Spring of 1898 I saw orchard after orchard of stunted, blighted pears. I asked several of the prominent growers as to the best means of fighting the disease from the start. The answer almost to a man was, "Starve them." I thought this was a peculiar answer, and doubted it, on general principles, and from a scientific standpoint. I met a man who had 25 trees, more or less, of Kieffer pears on the east side of his house, almost worthless from blight. On the west side he had 10 trees of the same variety free from blight, from which he picked last year 150 bushel baskets of fine pears. The trees were all the same variety and set at the same time. The 10 trees were in a chicken yard about 40x60 feet, or on an area of 2,400 square feet. The difference was the chicken droppings from about 60 hens, and the usual farmer's crop of Spring chickens. I told him he had the pears because he could not help it. The result is that he is converted from a starvationist to a feeder. After our talk on this subject last Spring he sowed his other orchard to cow peas, and his starved trees are loaded with blossoms and have an entirely different appearance. He will put in cow peas again this Spring and fertilize them also. I, believing an ounce of prevention is better than a pound of cure, washed my trees with lime, sulphur and salt, and also gave them 150 pounds each of nitrate and potash. I also washed a few with lime, sulphur and whale-oil soap. I should like to hear from some of your best pear growers on the subject of feeding or starving the pear; also the best kind of feed and quantity. I myself believe in feeding everything from the start, and, of course, increasing the quantity as the tree increases in size. This is the Almighty's way of doing it.

ANS.—A very plausible reason for the immunity of the well-fed trees in the above instance would be that their energy was expended in fruit production and not in a rapid growth of succulent wood. Another variety than the Kieffer might not remain immune under such stimulating conditions. As a general rule parasitic diseases attack weak and poorly-fed plants in preference to strong ones, but the Pear-blight bacteria appear to prefer rapidly-growing trees, as the germs find a ready entrance in soft-textured wood.

SPRAY with "EMPIRE-KING" OR THE GARFIELD KNAPSACK
and bugs, worms, blight, etc., will have no terrors for you. Best construction, perfect agitators, no scorched foliage. We make all sizes and styles. Free Book on Spraying. Agents wanted.
FIELD FORCE PUMP CO., 2 Market St., Lockport, N. Y.

A POTATO BUG
is most useful when he is dead. Kill him with "BOXAL," and prevent blight by the same same operation. $1 buys 10 pounds.

TRADE INDURINE MARK
It Costs 65 Per Cent Less

to paint your buildings with Indurine Weatherproof Cold Water Paint than to paint them with lead and oil. When you are done you will have a more durable, better looking and more satisfactory job. You can apply "Indurine" yourself and save the labor and expense of an expert. It is a dry powder and is quickly prepared by simply mixing it with cold water. Made in white and colors. For inside and outside use. It will not rub, scale, crack, blister or soften with age. It is better than anything of the paint kind for houses, barns, dairy buildings, poultry houses, picket or board fences, etc. Learn more about it before you do your spring painting. Write at once for sample, color cards, circulars and testimonials. Ask your dealer for "Indurine." If not there, write us direct and we will see that you are supplied.

Hope Farm Notes

CORN PROBLEMS.—A reader in New York asks some good questions:

"Would the Hope Farm man advise treating seed corn with formalin for the prevention of smut?"

No, I would not. It would probably do little if any good. With the oats these smut germs are on the seed—much the same as the scab germs are on the potato tuber. We aim to destroy them on the seed. Otherwise the smut may start shortly after the seed sprouts, and cripple the plant all through its life. The Corn smut, as I understand it, is different. These germs enter the plant mostly from the outside, floating in the air and settling upon the ear, where they develop and grow. We soak potato seed to prevent scab, and we spray the vines to prevent blight. As I understand it, Corn smut gets at the plant much as Potato blight does, only we cannot save the thick, big stalks by spraying.

"Last Spring the Hope Farm man told of his experience in treating seed corn with tar to prevent crows from pulling it up. He reported it a success. He also said he used Mapes corn manure broadcast. Last Spring, before and after plowing my corn ground, it was visited daily (I might say hourly) by some crows, until I broadcast 400 pounds per acre of Mapes corn manure, and after doing that not a crow did I see on that ground all Summer. I have often thought possibly it was the fertilizer instead of the tar that kept the crows from this cornfield."

We used thick gas tar on the corn. It was thinned a little with water—the corn was well smeared with it and then dried out by mixing with wood ashes. This left a thick, black coating over the seed. The crows pulled up a few hills and tasted the corn, but I doubt whether they swallowed a kernel. They quickly spit it out, and it was the cause of many violent caws at the caucus they held later in the woods. I have never known fertilizer to keep crows away, though I can understand how a good mouthful of it would make them tongue-tired. If it were bunched up around the hill they might taste it. Crows are very wise birds, and a little thing will often fill them with suspicion.

STUFFING THE SOIL.—The same reader also asks this question:

"I have a piece of ground in rye now, and wish to plant it to strawberries one year from this Spring. What course would I better pursue to get it in the best condition for planting at that time, the soil being a clay loam, facing the east?"

Here in New Jersey, if I were short of fodder, I would cut that rye early for hay. Then I would plow the ground and sow cow peas in drills. Early Black variety would be best. The peas would be cultivated as long as we could get through them. This would not only give a better crop of peas, but would largely kill out the white grubs. At the last cultivation of the peas I would sow a mixture of oats and Crimson clover among the cow-pea vines, covering the seed with the cultivator. I would rather have southern Winter oats if I could get them. The Early Black pea drops its leaves quite early, and in most seasons the oats and Crimson clover would start. The oats make a heavy growth through the Fall and early Winter, but die out in March. This, I think, permits a better preparation of the soil for strawberries than when rye is used. In this wet season, for example, the rye made such a start before strawberry ground could be fitted that I did not feel that we could do a good job until the rye was cut and hauled off. Remember, that I speak for the latitude of northern New Jersey.

FARM NOTES.—Still raining! Day after day the water pours down. Sundays are usually clear and bright. I suppose there are many farmers, who, if they had their own way, would have the sun illuminate work as well as worship! The stock of "indoor jobs" is about exhausted. . . . . Cherry blooming came right in a long hard rain. I do not look for much fruit, as a result of this drenching. The trees were heavily loaded with flowers. A wet season with us usually rots the cherries. . . . . The apple trees are covered with flowers. What a glorious thing it is to see great masses of pink and white color scattered over the valley, with the petals falling like a snowstorm! Our Greening orchard looks well. Last year it "went dry," but we gave it good care. Now, we shall spray it and hope for a good yield of this delicious fruit. . . . . Those Florida cabbage plants are thriving. They are without doubt ahead of the hotbed or coldframe plants. The thick, chunky workers usually have better staying power than the tall, "leggy" citizens. Speaking of Florida, Uncle Ed writes that his potatoes are drying up. Not a drop of rain for a month or more. . . . . A friend in New Hampshire has sent me a few bushes of blueberries. He has cultivated them for several years—thus developing fine, large fruit. We have set them out carefully near a stone wall. A fruit plant or a flowering shrub is a beautiful reminder of an absent friend. I want to make our roadside a plant album from friends all over the country. . . . . Little "Ape," the heifer's first calf, weighed only 57 pounds when one day old. He was so poor and thin that he hardly seemed worth raising. He milked the kicker, Julia, so well that when sold at 28 days old he weighed 99 pounds and sold at seven cents. Julia nursed her own calf most of the time also. The trouble with Ape was that he got a poor start. Still, his grandmother, Julia, has given him an inheritance of "kicking" ability that should take some of the kinks out of any rough pathway. . . . . Even the early potatoes are not all planted yet. We have, however, put them in well. I hear some complaint of rot in early potatoes, and it looks as though there will be a time in August when prices will be high.

CHICKEN FACTS.—A good friend who has had "bad luck" with chickens wants to know how the Hope Farm chicks act in the brooders. When you force us to tell the truth in that way I must admit that the brooder has been the scene of a tragedy. You will notice that I haven't bragged about our little chicks. No use blowing a horn over the dead. We started with 103 chicks in the brooder, and now have three left—under a hen. What killed the 100? Various things. They were never strong to begin with. We bought the eggs and paid $10 for the lot. There you have $3.33 for a single bird! They were never thrifty, but moped around, and when they were tired of that, lay down and died. Our own eggs are much better. Out of 172 fertile eggs 154 hatched, and only four have been lost in the same brooder which witnessed the former wholesale slaughter. You never saw a livelier lot of chickens. There is a sore place on my leg which indicates to me the chief reason for this lively crowd. It is where Don, the Wyandotte rooster, spurred me when I went to look at the egg record of his family. The sons and daughters of a nine-pound bird that is willing to tackle a 175-pound man will not fall down and die without a struggle at least. The fighting blood in that old chap does those chicks more good than the lamp under the brooder! What a great privilege it is to have fight and kick in one's pedigree, so that they may be turned to worthy ends!

MAKING FACES.—I am not going to refer to the habit some children and young women have of screwing up their face when there is a screw loose in the temper. I refer to the good folks who put up a smile and a brave front though the wolves are gnawing at their hearts. Here we have a letter from a Jerseyman. This man leads the singing in a Methodist church in a country place:

"I often see you (in my mind) sitting on the fence, or stone wall (which was it?) that Sunday dreaming and building castles in the air, and feel like taking a seat alongside of you. After coming home from Sunday school and church, eating a hearty dinner, and taking a nap for 15 minutes, there is nothing I enjoy more than taking a stroll down through the fields with my two dogs, and they seem to enjoy it, and know when Sunday afternoon comes as well as I do. But we have not indulged in that pleasure much this Spring, as we have only had one clear Sunday out of the last nine. That puts me in mind of an incident that occurred at church last Sunday. Everyone was feeling the effects of the weather, and looking a bit blue. As I got up to announce the first hymn, my wife nudged me and said: 'Sing Some of these days the skies will be brighter; Some of these days our hearts will be lighter,' etc., (a beautiful hymn). As I announced it a smile spread over the faces of the congregation like a ray of sunshine, and then when the minister began to preach, and announced that grand old hymn, 'From every stormy wind that blows; From every swelling tide of woes,' etc., the ray still brightened till everybody was in good humor." W. P.

For all the sport they make of me for sitting on a stone wall there are plenty of farmers who find rest for body and brain in looking off over the valley. We have great and noble thoughts on the hills. If we could carry some of these thoughts down into the dead level of common life how we would stir up this world! Somehow we drop most of them as we walk down hill. You see this man's wife nudged that idea into him. These wives are responsible for a good share of the worthy things that men start. I have often seen a farmer's wife halt her husband before he goes into church or before company and dust him off with her handkerchief, or straighten his necktie. It is a good thing for man that woman can also dust up his morals and good intentions from time to time. H. W. C.

See Publishers' Announcement, Page 381.

A TEXT BOOK OF PLANT DISEASES, by George Massee, of the Royal Herbarium, Kew, London: New York. The Macmillan Co., price $1.60. The sub-title of this excellent work qualifies the diseases treated to those caused by cryptogamic parasites, by which is meant the various microscopic germs preying on useful plants. The whole subject is very thoroughly treated, both from a practical and technical standpoint. The number of destructive germs thus brought together for description is quite astonishing. The book will be very useful to the intelligent cultivator, as well as for the student, for whom it is primarily intended.

SWEET CLOVER.—Reverting to the recent Sweet-clover discussion, I have a letter from an Ohio correspondent who has the following to say: "In your review bulletin you speak of all clovers being excellent restoratives to worn-out land. Would not Bokhara or Sweet clover be the best to begin with upon totally unproductive land? I planted some small stalks upon the south side of a mound of rotten shale which had been piled up 10 years ago from a railroad cut. It made a marvelous growth, though the slope was so dry and poor that no weeds nor grass could grow upon it for 10 years. The tap roots of the clover run down 2½ feet, and this year it will ripen seed. I have never seen it grow in rich or cultivated soil, and I believe it is easily crowded out by other plants, preferring to grow in spots where nothing else can grow." JOHN CRAIG.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

For the land's sake, use Bowker's Fertilizers. They enrich the earth.—*Adv.*

DR. WALTER VAN FLEET, H. E. VAN DEMAN, MRS. E. T. ROYLE, } Associates.
JOHN J. DILLON, Business Manager.

SUBSCRIPTION: ONE DOLLAR A YEAR.

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs.

"A SQUARE DEAL."

We believe that every advertisement in this paper is backed by a responsible person. But to make doubly sure we will make good any loss to paid subscribers sustained by trusting any deliberate swindler advertising in our columns, and any such swindler will be publicly exposed. W protect subscribers against rogues, but we do not guarantee to adjust trifling differences between subscribers and honest, responsible advertisers. Neither will we be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent us within one month of the time of the transaction, and you must have mentioned THE RURAL NEW-YORKER when writing the advertiser.

Name and address of sender, and what the remittance is for, should appear in every letter.
Remittances may be made in money order, express order, personal check or bank draft.
THE RURAL NEW-YORKER,
409 Pearl Street, New York.

SATURDAY, MAY 25, 1901.

As will be noticed on page 377 six more of the oleo rogues who try to sell their stuff as butter have met with their deserts. These rascals pretend to be expressmen. The only "express" business they do is to try to squeeze bogus butter through the meshes of the law. A period for reflection in jail, or a fine of $150, will do them good. Among the last batch was a man named Satanstein. Surely any man who will engage in this fraudulent business is a fit stone to carry Satan's mark.

*

WE learn from the papers that Hon. D. B. Henderson, speaker of the House of Representatives, is going to Europe for a brief visit. Mr. Henderson appointed J. W. Wadsworth, the friend of oleo, chairman of the committee on agriculture. Let us anticipate Mr. Henderson's home-coming. After being away from America for several weeks his first desire will be to know the sentiments of the people. Why not make things easy of comprehension by having thousands of letters on file at Washington telling him that the farmers want at the head of that important committee—a friend of the farm rather than a friend of the oleo factory. That sort of a home greeting would impress the Speaker, and oil the bearings of his duty!

*

PROF. Stedman's story of the way his name was used in connection with that "moth trap" last week is a good illustration of the impudence or "cheek" of some men. Prof. Stedman wrote out his experience with one insect only. The trap man put him through several stages, and finally had him endorsing the trap for the most impossible things. This man reasoned that Prof. Stedman would not bother about a small thing, but would let the statement go rather than take the trouble of making clear what he did say. If more of our public men would make a serious business of exposing these white lies and whitewashed facts, modern business would be put on a higher plane. Why is it that men who have goods to sell think they must tell big stories in order to attract attention? Cannot honest goods be sold honestly?

*

THE export trade of this country has reached enormous proportions. During the last fiscal year $1,370,763,571 worth of American goods were sent abroad, 61 per cent of them being products of the farm. Only seven per cent of these exports and 13 per cent of the imports were carried in American ships, vessels under the flags of Germany and England taking the greater share. During the past few months American capitalists have been securing control of steamships now sailing under the English flag. They have already bought the Leyland Line and have probably secured the fleet of the Atlantic Transport Company. It is said that these ships already land on the London docks over 5,000,000 tons of freight per year. If a new system of docks can be built in London the cost of handling can be considerably reduced, so that these ships will carry even more of American exports than they now do. It would seem as though England had seen her best days as a shipping or sea-carrying nation, giving way to this country. We seem destined not only to feed the world, but to carry the food to our customers as well. Vast changes and developments of industrial life are now going on, and old traditions and world-wide habits are being carried away by the ebb and flow of the tide of international trade. We must remember that the rock foundation upon which all these vast enterprises rests is the welfare and comfort of the American farmer. The money that is buying ships, building docks and changing the world's industry came originally out of the soil!

SOMETHING like 250,000 boxes of apples were sent to New York from the far western States last year. These apples gave good satisfaction, and there will be more of them this season. The Colorado apple growers in particular have their eye on this box trade. Experiments will be made next Fall with eastern apples packed in boxes. Dealers here feel sure that in time a good trade can be developed for these smaller packages. There is no room in the average New York flat for a whole barrel of apples. The fruit costs too much when bought by the measure or dozen, but a box of fair size can be kept on the fire-escape. Since the various crackers and hard biscuits were put up in small, convenient packages the trade has been greatly increased. So it will be with apples. Will eastern growers let the western men secure all the advantages of this trade?

*

Two years ago a committee consisting of two men called at the office of a transportation company to ask for better rates and service. There were other members of this committee, but they failed to come. The transportation people listened politely, but it was easy to see that they reasoned in about this way: "Here are only two men. If the farmers of this section cared much about this more of them would be here—at least they would make their interests known. We need not lose any sleep over this!" This year the same two men came back with seven others—all men of substance and business. They filled the room, and as the same transportation people sized them up they concluded that there was no play or bluff about their demands. When will farmers wake up to the fact that in dealing with those who handle their goods they are individually weak but collectively strong? Get together for business! That is the agricultural watchword to-day!

*

WE sometimes hear young men grieve because they cannot borrow money on their personal note. Could they but know it, the ability to borrow money easily would most likely prove a curse rather than a blessing to them. We believe that five young men have been hurt by easy credits where one has been permanently held back by the necessity of keeping within his means. Borrowing comes easy when one is young and hopeful. We assume an obligation as we put on a new coat. We think we can pull it off as easily, but all too often we wake up to find that it has fastened to one's life like a cancerous growth and cannot be shaken off. After many years of experience and observation we are convinced that in most cases it is a sad mistake to lend money to young men who can give nothing but a personal note without security. The boy who is capable of handling borrowed money to advantage will be able to make security for it. He will probably never make such security until he is obliged to do so.

*

SEVERAL months ago the papers reported a German chemist who gave advice about shipping American apples. He said that such apples should be sprayed about the stem end with a two-per-cent solution of peroxide of hydrogen, and then carefully wrapped in paper. A weak solution might possibly retard decay somewhat, but too much would bleach the red varieties and hurt their sale. Once let foreign consumers learn that our fruits are "treated with chemicals" and we should lose trade immediately, even though nothing but sugar and water were used. For this reason alone all such schemes should be discouraged. There are some varieties of apples peculiarly adapted to the export trade. They grow better in some localities than in others. If they are picked at the proper time without bruising, and held at a low temperature while in storage and during shipment, they will reach the other side in good condition. No other apples should be sent, and no spraying or "dipping" will help them.

*

WE do not always realize just why we do this or that. There is a slow process of evolution in our agricultural practice as well as in the development in nature. The corners are cut here and there, until finally, almost unconsciously, we have a practice or custom evolved that may be the very best for a community. The hard, stern, immutable law of the survival of the fittest deals with us unmercifully sometimes. While there is much danger of getting into ruts when one stays at home continually, yet there may be danger in seeing too much. We are not always able to see the causes that have led up to success, and are thus misled, and find later that our environments and abilities are not equal to the emergency, and failure follows. It takes good judgment to hear of large experiences of others, to read of great results, take it, digest it, and not become dyspeptic. If one talks or writes of his failures the listener or reader at once forms an opinion that he can get nothing from such a source, he turns the page over and reads of a cow that has just made 28 pounds of butter in a week, and is delighted with a possibility. His own cows, however, are not making seven pounds. How long do you suppose it will take this man to get to his momentary ideal? We are most benefited by contact with those who are doing just a little better than we are, an occasional sight of the game gives the hunter and dog courage to pursue.

*

WHILE airing their differences before the Industrial Commission the great tobacco manufacturers let out some information as to the business methods of a trust. The tobacco trust undertook to "freeze out" a rival concern. Its agents went to jobbers and retailers, and offered five per cent better terms if they would handle only trust-made goods. If they refused they were told that they could not handle any of the brands made by the trust. As a result the trade in independent goods was described as follows:

When a customer asked for an independent brand, such dealers would look around fearfully, as if they were about to commit a crime, and then sneak out the desired brand from under the counter, or from such other out-of-the way place. To these retailers the United States company was obliged to ship its goods in plain cases, without any marks which would serve to identify the contents as the product of an independent concern. When things had come to such a pass that a dealer sold a non-trust brand of tobacco with precisely the same guilty air with which he would pick a lock or commit a theft, and with just as much fear for the consequences, it was certainly time for remedial legislation.

We agree with that last statement. It wouldn't hurt our feelings if every man who sells any sort of tobacco could be made to feel like a thief. What hurts us is the fact that these same trust methods may be applied to the sale of food or other necessary articles.

*

BREVITIES.

Uncle Daniel used to pray,
In a humble, shambling way,
Half ashamed of what he said.
I can see his old, white head,
Bending o'er the table yet.
"Lord," he said, "make us forget
Them things that we want ourselves;
Help us reach up on the shelves.
Where we've tucked away the things
That a godly living beings,
Give us strength to hand a share
Of them treasures laid up there
To the poor and weak and sick
Use our hands to take your pick,
So we won't make fight or fuss,
For you give it all to us!"
Uncle Daniel at his best
Gave his nouns and verbs no rest;
Strangers tittered at his prayer,
But he had the essence there
Of the truth which wise men preach,
Pray all round, but never reach.

BUSINESS hours belong to the boss.

READ the "kicking" cures on page 382.

GREAT stunts are seldom performed by runts.

THE baby in the cradle is down to bed rock!

MY son, work first, and talk about it afterwards.

WHO can reach contentment without a small amount of cash?

HAVE plenty of faith, but don't try to manufacture it into "cheek."

CALL your fellow man brother with the heart rather than with the mouth.

PLANTS must take their food in the form of soup—as Prof. Craig says on page 373.

BE sure to read Mr. Cook's talk on milking—page 383. Always hold part of your energy in reserve.

SOME people never do their best until they are crowded into a corner where they must exert themselves.

WHY does the so-called "business" man drop most of his ideas of successful business when he goes to farming?

WE wish the patient horse could come and tell you how it feels when you neglect the wagon wheel until it loudly squeals.

SUPPOSE everybody leveled up or down to your own standard of duty-performance! Would the world be better or worse?

THERE has been so much questioning about the use of Cowhorn turnips as green manure that we hope to print the whole story soon.

CAN anyone name a case where stock of any kind has been injured by the drippings from sprayed trees? Were they poisoned by eating the grass?

MR. COOK tells us truly that some men hustle most when their muscles are moving least. We cannot see the brain work—we only see the results of mental hustling.

NO, we would not soak cut potato seed in either formalin or corrosive sublimate. That soaking should be done before the seed is cut. Dust sulphur over the cut seed.

READERS will regret to learn that our Mr. Van Deman recently threw his shoulder out of joint. He is still prepared to put a shoulder to the wheel on all hard fruit problems.

ON page 371 Mr. Keesling tells how ineffectual moth traps were made useful by a dose of printer's ink. A good many other traps lose their danger when treated with the same specific.

TENNYSON truly tells of people who climb "from their dead selves" to reach higher things. The trouble with some people is that they have so much self-esteem that they kill their best selves with kindness and then carry the corpse around with them.

Events of the Week.

DOMESTIC.—A fire at Dawson, Alaska, reported May 8, burned a large number of buildings, and caused a loss of $75,000. . . . . There is a severe outbreak of smallpox among Indians at Sitka, Alaska, and the disease is spreading. . . . . A gun is being built for the United States Government that will carry a projectile weighing 2,730 pounds a distance of 21 miles. If successful 40 of the cannon will be built for coast defense. . . . . At Berkeley, Cal., 18 cases of smallpox were reported in the State Institute for the Deaf, Dumb and Blind May 9. On the same date, 15 new cases and two deaths from the same disease were reported in Greater New York. In addition to existing sources of contagion, smallpox is now coming into New York on Italian steamers, which are bringing an unusual number of immigrants, and the sanitary officials find their quarantine facilities taxed to the utmost. . . . . May 9, two persons were killed by lightning, several thousand dollars worth of crops destroyed, and a dozen barns demolished, during a storm in Lawrence and Mercer counties, Pa. . . . . The explosion of a locomotive boiler at Mount Bedford, Pa., May 11, caused the death of four men. . . . . A Florence (Ariz.) dispatch says that the Gila River, on the Sacaton Reservation, has gone dry, and no grain will be harvested by the Indians. Great destitution will ensue. . . . . May 12, fire destroyed over $800,000 worth of property, chiefly lumber, along the Rouge River in Delray, a suburb of Detroit, Mich. . . . . A trolley car, on which were 115 persons, was wrecked in descending a steep hill at Fort Lee, N. J., May 12, and nearly all of the people were injured. It is thought the conductor will die. . . . . Jacksonville, Fla., is to remain under martial law indefinitely. This is considered necessary because hordes of tramps and disreputable characters are flocking into the devastated city, in the hope of sharing free rations without work. . . . . The steamer City of Paducah struck a snag in the Mississippi River near Grand Tower, Ill., May 13, and sank in five minutes; seven lives lost. . . . . May 15, mob violence in Albany, N. Y., resulting from an extensive street-car strike, grew beyond the control of the local authorities, and State militia was ordered to the scene of the riot.

ADMINISTRATION.—Two claims for indemnity, growing out of the blowing up of the Maine, which have been filed with the Spanish Claims Commission, may bring the whole question of responsibility for the destruction of the Maine before that tribunal. Senator Chandler, the President of the Commission, after reading the briefs in the cases, believes that the body over which he presides has jurisdiction. The question at issue is whether Spain or the United States is responsible for the damage inflicted in the destruction of the battleship. If Spain, then the United States, having assumed responsibility for claims of American citizens against Spain growing out of the disorders in Cuba, will be held liable. If the destruction of the Maine was not due to Spanish agencies, but to some internal accident or defect, then the claim could not properly come before the Spanish Claims Commission, and no claim for damages would hold. The singular feature of the business is that the law officers of the United States Government, in opposing the claim, may be compelled to take the position that Spain was not responsible for the blowing up of the Maine, and that the report of the Sampson Court of Inquiry was not a final determination of the question for the purposes of law. It will be the first time that the subject has ever been considered with all the rules of evidence before a judicial tribunal.

PHILIPPINES.—Detectives and the police have broken up a band of American brigands, who have been operating in the province of Pampanga, north of and not far from Manila. George Raymond, Ulrich Rogers and Oscar Mushmiller have been captured, and Andrew Martin, Peter Heise, George Muhn and two others are still being pursued. The band sometimes represented themselves as American deserters and at others as American soldiers. George Raymond wore the uniform of a captain. Raymond and Martin were formerly policemen in Manila.

GENERAL FOREIGN NEWS.—Heavy snow fell in parts of England May 7, endangering Spring crops. . . . . Census returns for England and Wales are practically complete, and show a total population for the two countries of 32,525,716. This is an increase of 3,523,191 over the population of 1891, a gain of 12.15 per cent during the 10 years. . . . . Violent earthquakes in the vicinity of Mount Etna, Sicily, are thought to presage an eruption.

FARM AND GARDEN.—J. W. Bailey, Oregon State Food and Dairy Commissioner, will make a strong representation to Secretary Wilson during his visit to the Pacific coast, for modification of the proposed Philippine tariff so as to admit butter into the Islands free of duty, and put a charge of 10 cents a pound on oleomargarine and all other imitations of butter. The schedules recommended by the Taft Commission put a duty of five cents a kilo of 2 1-5 pounds on butter and six cents a kilo on oleomargarine. The differential is only one cent a kilo, or a little over half a cent a pound, in favor of butter. Dairy interests all over the country have protested to the War Department against the discrimination, which is clearly for the benefit of the packing houses of the Mississippi Valley. Commissioner Bailey has the support of the butter manufacturers of Oregon in the effort he will make with Secretary Wilson in their behalf.

The twenty-seventh biennial session of the American Pomological Society will be at Buffalo, September 12 and 13, 1901, the exhibition being held in the Horticultural Building at the Pan-American Exposition; exhibits will be eligible to exposition awards.

The New York State law prohibiting the admission of nursery stock unless accompanied by a certificate from the entomologist of the State whence the goods are shipped, is embarrassing the nurserymen of several States where there is no such office as State entomologist.

Reports to the Department of Agriculture show that the average condition of Winter wheat on May 1 was 94.1. The total area under cultivation is 28,267,000 acres.

A Summer school in nature study is arranged by the School of Agriculture and Horticulture at Briarcliff Manor, N. Y., opening July 23. The course is offered especially to school teachers.

Some time in June O. G. Van Winkle will hold a strawberry carnival at Burlington, Iowa, at which he will exhibit specimens of 200 varieties of his own growing. All berry growers are invited to exhibit or participate in the meeting.

The East Tennessee Farmers' Convention was held at Knoxville, Tenn., May 21-22. It was one of the most representative agricultural gatherings ever held south of the Ohio River.

THE STRAWBERRY CROP.

Late in Maryland.

Last season's drought and heat were very severe on plant growth, and we have a very poor stand of plants on the rows. The weather has also been very unfavorable this Spring for plant growth, also for the fruit. Many blooms have been killed by frost and freezing; it looks at this writing as though we will not have over half a crop, and quality of fruit not the best. The season will be about 10 days late; prospect for other fruits good.

Marion Sta., Md. J. W. H.

Short in Virginia.

We think that there will be a short crop of strawberries this year. There has been no killing frost since bloom appeared, but the very severe drought of last Summer killed out a great many plants of the new beds, and the beds are very much broken. The quality of the fruit will depend on the weather from now on. A few of the farms are picking a crate or two this week, but there will be no general picking before next week.

Churchland, Va. J. E. W.

The Crop in Northern New Jersey.

All indications point to a half strawberry crop only in this section, the dry weather of last Summer having damaged berry patches to a great extent. Only a few careful growers will have anything like a full crop. In fields that were left uncovered during the Winter the plants are nearly extinct, especially in beds of over a year's standing. The strawberry crop, which, last season, proved exceedingly profitable, has caused a very large acreage to be planted this Spring, a great many rushing into the business who scarcely know a strawberry plant when they see one. This move will, of course, have but one effect, that of glutting the markets with small worthless berries of poor quality a year hence, after which they will again leave the field open for the careful grower, and go back, sick at heart, to their old calling. By the careful grower I mean the man who prepares his ground properly and sets pure pedigree stock and cultivates frequently during the Summer, not allowing a weed to get a start on him; then when Winter comes mulches his plants to protect them from the thawing and freezing of the cold months. The following Summer, if conditions are favorable, such a man can go to market with a load of beautiful berries, dispose of them and return home again, while the careless grower, who plants scrubs which he can procure for little money, puts them on poor ground poorly prepared, and allows the weeds to master him during the Summer, goes begging around, offering his fruit at any price, and never gets home till night and then, probably, with half his load unsold. Why would not such growers become disheartened and rush out of the business faster than they rushed in? Still, their chances are just as good as their neighbor's if they would only go about it in the right way. In this section (Sussex Co., N. J., near where the three States, New Jersey, Pennsylvania and New York meet), Bubach seems to be the stand-by, although some of the newer varieties, such as Sample, Bismarck, Excelsior, etc., have been quite largely planted this Spring by those who wish nothing but fancy fruit. The majority of those, however, who have rushed into the business, got their plants from some old beds, not even knowing whether they were perfect or imperfect varieties. I have at present over 20 kinds, new and old, on the farm, testing them with a view of determining their value on my soil. Nearly all my fruit is sold in Port Jervis, N. Y. J. M.

Tri States, N. Y.

THE POTATO CROP.

There is a shortage in acreage in our neighborhood; about one-third less than last year. The early planted potatoes are coming up poorly; some few rotting, others coming very uneven and weak, especially those planted before the week of rain. I have planted but two acres this year; have been planting four to five for several years, but have had no profit from the crop for about three years. Last year the crop was very light. We use from 800 to 1,400 pounds of high-grade potato manure to the acre. I have talked with two of our prominent farmers about potatoes; they are of the same opinion as myself in regard to the crop and conditions. H. K. G.

Columbus, N. J.

I have not learned of anyone having to replant in this vicinity; the long cold Spring delayed the farmers from planting as early as usual, and only a few have their crop above ground. In regard to the acreage it compares very favorably with last year. The Spring has been so cold and wet that seeding of all kinds has been delayed, and what seed has succeeded in coming through cannot grow very rapidly. Although the potato crop was almost a total failure in this vicinity last year, owing to the very dry weather and hot sun, the farmers are preparing to plant as many acres as usual, hoping for better results this year. C. F. H.

Bridgeton, N. J.

From personal observation and from inquiry I am satisfied that not more than one-half of the number of acres planted last year have been planted this. Probably the majority of farmers about here have put in their usual quantity—from one to four acres—but others who planted largely last year—from 10 to 30 acres—have planted very few, and some none at all this year. Last season was very unfavorable for growing potatoes in this section owing to the long drought, hot weather and the bugs; some had fairly good yields, but with others the crop was a complete failure. This year, owing to the cold and extremely wet weather which still continues, but few potatoes were planted before the middle of April, and many not until May 1. Those planted early are just coming up, and, I judge from my own, which were planted on April 12, are coming all right. Perhaps some seed planted on low ground may rot, but it is too early to determine. Other seeds have come up well, better than usual. Oats and peas, beets, carrots, onions, spinach, etc., are looking well. There is a good show for grass, grain and fruit. Peach trees are full of blooms and apple trees just putting out. I hope and trust bugs and insects will not be plentiful as they were last year. Potato bugs were something fearful; they seemed to thrive on Paris-green. I used sulphur and lime with it on potatoes and vines, and had fairly good crops. I also used sulphur on potato seed last year and this; had much less of the scab. D. C.

Huntington, N. Y.

Justice for Oleo Rogues.

The Department of Agriculture in this division has persistently kept up the fight against wagon men coming from New Jersey selling oleomargarine in this territory under the guise of expressmen. During the past week five men were arraigned for trial in the Special Sessions Court, with the result that three of them were fined $150 each or 60 days in jail; one sent to the City Prison for three months without any money penalty whatever, and sentence suspended upon another, the latter being a boy upon one of the wagons toward whom the court deemed it wise to be lenient. This brings the total up to about a dozen wagon men from New Jersey who have been detected and fined in selling oleomargarine during the past Winter. Warrants have been issued for several others, and the department feels confident that the illegal traffic in oleomargarine has received a severe setback through the heavy penalties inflicted by the courts, as the larger number of the dozen convicted had to serve a term in jail. John Colligan, Jersey City, three months in jail; George Wilson, Jersey City, $150 or 60 days in jail; James Mihim, Jersey City, $150 or 60 days in jail; George Warren, Jersey City, $150 or 60 days in jail; William Bradley, Jersey City, sentence suspended; James Hutcheon, 57 Nostrand Ave., Brooklyn, $200.

Government Crop and Weather Report.

Unusually cool weather has prevailed in the Mississippi Valley, with damaging frosts in the northerly section. On the western plateau and Pacific coast districts, the warm weather following the previous heavy rains, has made conditions highly favorable to vegetation. Corn-planting in the Central West has been delayed by the cold. In Nebraska, Kansas and southern Missouri, wheat is suffering slightly from drought. The grain is heading in Tennessee and southern Kansas. Oat seeding in the extreme North is still going on. The southern crop is being harvested, but is reported light on account of previous drought. In the Middle Atlantic States and Ohio Valley they are growing finely. Conditions in the cotton belt are unfavorable, rain being greatly needed. Southern tobacco is looking well. Transplanting in the Carolinas is about finished, and the work is being done as far north as Maryland. In New York farm operations of all kinds have been going on as rapidly as possible between showers; wheat, rye and grass in most sections are looking fine. Local hailstorms have done considerable damage in the Carolinas. In Georgia rice has been damaged by the cold weather. Fruit is dropping badly, but still there is plenty on the trees. In southern Jersey some seed potatoes are rotting. Strawberry outlook there and in Maryland is promising. In Pennsylvania the acreage of corn is large, and prospects for tree fruits favorable.

Wheat and rye are looking fairly well at present; judging from appearances now there will be an average crop. The newly-seeded grass fields are not looking very promising. We sow Timothy in the Fall and clover in the Spring on both light and heavy land. W. E.

Columbia Co., Pa.

ROADSIDE TREE LAW.—We are asked to print the Pennsylvania law regarding planting trees on roadsides. Here it is: Any person liable to road tax, who shall transplant to the side of the public highway on his own premises any fruit, shade trees or forest trees of suitable size shall be allowed by the supervisor of roads where roads run through or adjoin cultivated fields, in abatement of his road tax, $1 for every four trees set out, but no row of elms shall be placed nearer than 70 feet; no row of maples or other forest trees nearer than 50 feet, except locust, which may be set 30 feet apart, and no allowance as before mentioned shall be made unless such trees shall have been set out the year previous to the demand for such abatement of tax, and are living and well protected from animals at the time of such demand. Any trees transplanted to the side of the public highway as aforesaid in the place of trees which have died, shall be allowed for in the same manner and on the same conditions as in the preceding section. Abatement of highway tax limited to one-fourth of annual highway tax.

PROSPECTS IN PENNSYLVANIA.—We are getting a little of the rain the farmer at Hope Farm has been writing about, and we have had to quit farming for a few days past. The month of April was very dry, but May came in wet and still continues so. The rain is putting planting back; not many potatoes planted yet and no corn. I hear that some have not got all of their oats sown yet, but I think most of the oats were sown in April; there are always a few who are behind. Apple trees are not in blossom yet; I was looking at ours today and found them full of buds; think the prospect good for a big crop. Last year we got none. We are the only ones who grow wheat about here, and it is looking fine, better than last year at this time, and we thrashed 114½ bushels from 4½ acres. Rye is looking nice, better than last Spring. I think we had a little more snow during the Winter. Meadows are not looking well; new seeding is very poor. Pastures were grazed so close last Fall that they are in very poor shape. One pasture field where sheep ran last season is killed out so there is no grass on it this Spring, and the neighbor who owns it told me he would have to sell his sheep, as he had no other pasture for them. Our pastures are in fair shape. We commenced to feed our cows grain the last of July and kept it up all the Fall, so our cows did not graze so close, and I think it paid us. We are still holding the fort and making butter at our new factory.

Hop Bottom, Pa. E. P. B.

Woman and Home

From Day to Day.

THE WESTERN BOY'S LAMENT.

I wish't I lived away down East,
Where codfish salts the sea,
And where the folks have pumpkin pie
And apple-sass for tea.
Us boys who'se livin' here out West
Don't get more'n half a show;
We don't have nothin' else to do
But just to sort of grow.

Oh, if I was a bird I'd fly
A million miles away,
To where they feed their boys
On pork and beans three times a day;
To where the place they call the Hub
Gives out its shining spokes,
And where the folks—so Father says—
Is mostly women folks.
—Eugene Field's "Sharps and Flats."

*

CHAMELEON serge is one of the new materials; it is a close weave in changeable colors—blue and green, leaf green and violet, or brown and red. Taffeta straps are used to trim these serges. We also see a revival of calico this year; not sleazy cottons in ugly patterns, but crisp French and English prints, in a variety of beautiful colors. They have the smooth glazed surface of chintz, and many of them have handsome borders, as they had 15 or 20 years ago. The borders form a very pretty and effective trimming, more suitable to the material than lace or embroidery.

*

A MAN recently caused a sensation in a Brooklyn street car by his ingenious baby carrier. He had an umbrella in one hand and a satchel in the other, while, dangling in front, apparently without any human support, was a contented baby. Closer investigation showed that the child was resting on a wicker seat closely resembling the top of a vegetable basket. To this two steel hoops were securely clamped, holding the child in, while a leather strap fastened to these hoops passed around the father's neck. It was the general opinion of those who saw the device that the Brooklyn man could give points to an Indian squaw on the best way to carry a papoose.

*

SOY beans are said to be one of the best muscle-producing foods grown, containing a large proportion of protein. The Japanese eat little meat, but the Soy bean forms a large portion of their diet, and to this is ascribed their energy and endurance, which forms a strong contrast to the comparative indolence of the rice eaters. The North Carolina Experiment Station gives the following directions for preparing Soy beans: Soak the beans, until the skin rubs off, and stir until the skins rise to the surface. Boil the beans, with or without bacon, until soft; then season with salt, pepper and butter, and serve. The beans make an excellent substitute for meat, as far as nutritive value is concerned.

*

EACH season we decide that, before another housecleaning time comes around, we will have all our implements and materials for the work on hand, and in good condition. One trifle, needed all the year round, but especially at cleaning time, is a broom cover of canton flannel—several, rather, that they may be washed as necessary. They are very useful for dusting walls and ceilings. Make a bag large enough to fit over the broom, using the soft nap for the outside; run a tape in the hem, by which it is drawn closely on the broom. Another good idea is to have a soap rack that may be hung on the edge of a pail; it saves soap, and also does away with the risk of falling on a slippery streak or bit of soap. These racks are sold in the large stores, or may be adapted from something else by a handy man. A small piece of oilcloth on which to stand the bucket when needful is another trifle that adds to one's comfort.

HANDKERCHIEF stock collars are among Spring accessories, some being made apparently of white hemstitched handkerchiefs with embroidered corners, others with colored borders. The stock is covered with folds of the material; two little corners furnish turnover points, and the other corners are twisted into a four-in-hand knot in front. With colored borders, one of the newest models has about one-quarter of the handkerchief falling like a cape in the back, from the top of the stock, while two ends are brought forward to tie in a knot in front. Their style depends entirely upon the way in which they are made; it must be owned that they rather suggest an old-fashioned sore throat on the part of the wearer.

*

THE advice offered by the elder Mr. Weller concerning widows was apparently no new thing, for in the State archives of South Carolina is a time-stained document addressed to the Colonial Governor, and bearing the date of 1733. It is signed by 16 young women, and reads as follows:

We, the humble petitioners, are at present in a very melancholy condition of mind considering how all the bachelors are blindly captured by widows and we are

3807 Misses' Five-Gored Skirt,
10 to 16 years.

thereby neglected, in consequence of this our request is that your excellency will, for the future, order that no widow will presume to marry any young man until the maids are provided for, or else to pay, each of them a fine for satisfaction of invading on liberties and likewise a fine to be levied on all bachelors as shall be married to widows. The great disadvantage it is to us maids is that the widows by their forward carriage do snap up the young men and have the vanity to think their

3723 Five-Gored Skirt
22 to 32 In. Waist.

merits beyond ours, which is a great imposition to us who ought to have the preference. This is humbly recommended to your excellency's consideration and we hope you will permit no further insults.

These dissatisfied maidens apparently considered that if the widow was not burned on her husband's funeral pyre, after the Hindu custom, she should at least be well roasted.

The Rural Patterns.

Tucked and pleated flounces are sharing popular favor with the gored style, and the skirt shown is well suited for girls' wear. The skirt is cut in five gores and is laid in an inverted pleat at the back. The upper portion fits smoothly and snugly, but the shaping provides a graceful flare below the knees. As shown the flounce arranged in groups of tucks is applied over the lower edge and makes a becoming and fashionable finish, but the skirt can be left plain when desired, as it is cut full length and extends beneath the flounce. To cut this skirt for a miss of 14 years of age 6¾ yards of material 22 inches wide, 6⅜ yards 27 inches wide, 6⅛ yards 32 inches wide or 3¾ yards 44 inches wide will be required. The pattern No. 3807 is cut in sizes for misses of 10, 12, 14 and 16 years of age; price 10 cents.

The woman's skirt with circular flounces is of advantage when making over fabrics which may have to be pieced, since the flounces would hide any joins. It is a very graceful shape, and is specially commendable for duck, piqué or linen skirts to wear with shirt waists. The skirt is cut in five gores. The wide ones, at each side, are fitted with short hip darts, and the fullness at the back is laid in an inverted pleat. To cut this skirt for a woman of medium size 11 yards of material 21 inches wide, 8¾ yards 32 inches wide, 5¾ yards 44 inches wide, 5¼ yards 50 inches wide will be required. The pattern No. 3723 is cut in sizes for a 22, 24, 26, 28, 30 and 32-inch waist measure; price 10 cents.

Out-of-Doors.

She knew that she ought to go out for the fresh air every day. She read a great deal about the necessity of exercise out of doors, and she believed in it theoretically. In practice, however, there were many days when she hardly stepped out of the house. There would be a bit of work that she wished to finish, or the weather was disagreeable. She lived on a farm, so there was no marketing to take her out. One Winter two things combined to make her get more air. She had two diaries given her at Christmas, and the horse went lame. She always kept a diary, but this year, as both those given her were very nice ones, she decided to keep both of them. One was to contain observations on nature. After a week or so she found that if she noted down only the things seen from the house windows her nature diary would contain little besides weather. So she felt the necessity of going out every day to get material. She did not go far, but she always found something of interest, if nothing more than the actions of a flock of snowbirds.

The other factor—the horse—was the cause of her taking an unusual amount of walking exercise. She lived more than a mile from the post office, and she liked to hear from it often. She had not supposed that she could walk so far, but she found it a benefit and a pleasure. Her conclusions at the end of the Winter were as follows: "Every woman ought to spend at least a half hour out of doors every day of her life, and especially during the Winter. If she cannot force herself to do it, knowing that she ought to, and that it will make her feel better, she should go to work and invent something to take her out, and to give her an interest in out-of-door life."

A Balsam Pillow.

PART II.

So April passed and May and June. The crops were planted, the vegetables in. Brie strained every nerve. She petted her hens, and coaxed every possible egg out of them, she studied the tastes of the two cows, she maintained a brave show of cheer for her ailing mother, but all the time she was sick at heart. Everything seemed closing in. How long would she keep it up?

The balsam firs of the hill grove could have told tales in those days. They were Brie's sole confidants. The consolation they gave, the counsel they communicated, were mute, indeed, but none the less real to the anxious girl who sat beneath them, or laid her cheek on their rough stems. June passed and with early July came the answer to Brie's many prayers. It came as answers to prayers often do, in a shape of which she had never dreamed.

Miss Mary Morgan, teacher in grammar school No. 3, Ward Nineteen, of the good city of Boston, came, tired out from her Winter's work, to spend a few days with Farmer Allen's wife, her second cousin, stopped one day at the Dorset's door, while driving, to ask for a drink of water, took a fancy to the old house and to Brie, and next day came over to propose herself as a boarder for three months.

"I can only afford to pay $7 a week," she said, "but, on the other hand, I will try not to make much trouble, if you will take me."

"Seven dollars a week; only think!" cried Brie, gleefully, to her mother after the bargain was completed, and Miss Morgan gone. "Doesn't it seem like a fortune? It'll pay Reuben's wages and leave ever so much over! And she doesn't eat much meat, she says, and she likes baked potatoes and cream and sweet baked apples better than anything. And there's the keeping room chamber, all cleaned and ready. Doesn't it seem as if she was sent here to us, Mother?"

"Your poor father never felt like keepin' boarders," said Mrs. Dorset. "I used to kind of fancy the idea of it, but he wasn't willin'. I thought it would be company to have one in the house, if they was nice folks. It does seem as if this was the Lord's will for us, her coming in so unexpected and all."

Two days later Miss Morgan, with a hammock and a folding canvas chair and a trunk full of light reading, arrived, and took possession of her new quarters. For the first week or two she did little but rest, sleeping for hours at a time in the hammock, swung beneath the shadowing elms. Then, as the color came back to her thin face and the light to her eyes, she began to walk a little, to sit with Brie in the fir grove, or read aloud to her on the doorstep while she mended, shelled peas, or picked over berries, and all life seemed to grow easier and pleasanter for the dwellers in the solitary farmhouse. The guest gave little trouble, she paid her weekly due punctually, and the steady income, small as it was, made all the difference in the world to Brie.

As the Summer went by and she grew at home with her new friend, she found much relief in confiding to her the perplexities of her position.

"I see," Miss Morgan said, "it is the Winter that is the puzzle. I will engage to come back next Summer, as I have this, and that will help along, but the time between now and then is the difficulty."

"Yes," replied Brie, "the Winter is the puzzle, and Reuben's money. We have plenty of potatoes and corn and vegetables to take us through, and there's the pigs to kill and the chickens will lay some; if only there were any way in which I could make enough for Reuben's wages, we could manage."

"I must think it over," said Miss Morgan.

She pulled a long branch of the balsam fir nearer as she spoke, and buried her nose in it. It was the first week of September, and she and Brie were sitting in the hill grove.

"I love this smell so," she said. "It is delicious. It makes me dream."

Brie broke off a bough.

"I shall hang it over your bed," she said, "and you smell it all night."

So the fir bough hung upon the wall till it gradually yellowed, and the needles began to drop.

"Why, they are as sweet as ever—sweeter," declared Brie, smelling a handful which she had swept from the floor. Then an idea came into her head.

She gathered a great fagot of the branches and laid them to dry in the sun on the floor of a little-used piazza. When partly dried, she stripped off the needles, stuffed with them a square cotton bag, and made for that a cover of soft sage-green silk, with an odd shot pattern over it. It was a piece of what had been her great-grandmother's wedding gown. Do you realize the situation, readers? Brie had made the first of all the many balsam pillows. It was meant for a good-by gift to Miss Morgan.

"Your cushion is the joy of my life," wrote that lady to her a month after she went home. "Everyone who sees it falls in love with it. Half a dozen people have asked me how they could get one like it. And, Brie, this has given me an idea. Why should you not make them for sale? I will send you some pretty silk for the covers, and you might cross-stitch a little motto if you liked. I copy some for you. Two people have given me an order already. They will pay $4 apiece if you like to try."

3822 Girl's Costume, 6 to 12 years.

3821 Fancy Shirt Waist, 32 to 42 in. bust.

This suggestion was the small wedge of the new industry. Brie lost no time in making the two pillows, grandmother's gown fortunately holding out for their covers. Then came some pretty red silk from Miss Morgan, with yellow filloselle for the mottoes, and more orders. Brie worked busily that Winter, for her balsam pillows had to be made in spare moments when other work permitted. The grove on the hill was her unfailing treasury of supply. The thickset twigs bent them to her will, the upper branches seemed to her to rustle as with satisfaction at the aid they were giving. In the Spring the old trees renewed their foliage with vigorous purpose, as if resolved to balk her in her purpose.

The fir grove paid Reuben's wages that Winter. Miss Morgan came back the following June, and by that time balsam pillows were established as articles of commerce, and Brie had a munificent offer from a recently established decorative art society for a supply of the needles, at $3 a pound. It was hard, dirty work to prepare such a quantity, but she did not mind.

As I said, this was some years since. Brie no longer lived in the old home. Her mother died the third year after Miss Morgan came to them, the farm is sold and Brie is married. She lives now on a ranch in Colorado, but she has never forgotten the fir grove, and the memory of it is a help often in the desponding moments that come at times to all lives.

"I could not be worse off than I was then," she says to herself. "There seemed no help or hope anywhere. I felt as if God didn't care and didn't hear my prayers; and yet, all the time, there was dear Miss Morgan coming to help us, and there were the trees, great beautiful things, nodding their heads and trying to show me what could be made out of them. No, I never will be faithless again, nor let myself doubt, however dark things may look, but remember my balsam pillows and trust in God."—Susan Coolidge in Colorado Weekly Times.

MOTHERS.—Be sure to use "Mrs. Winslow's Soothing Syrup" for your children while Teething. It is the Best.—*Adv.*

Rural Recipes.

Flannel Cakes.—One cupful of Indian meal, two cupfuls of flour, three of boiling milk, one-fourth of a yeast cake, one teaspoonful of salt, two tablespoonfuls of butter and one of sugar. Pour the boiling milk upon the meal and butter; let it cool; then add the flour, salt, sugar and the portion of yeast dissolved in four tablespoonfuls of cold water. Let it rise over night, and in the morning fry as you would griddle cakes.

Election Cake.—Rub into half a pound of sifted flour five ounces of butter, add a saltspoonful of salt, one cupful of sugar; mix. Scald two cupfuls of milk, and when lukewarm add one yeast cake dissolved, and two eggs well beaten. Make a hole in the center of the flour, pour in the milk mixture, stir in a little of the flour; cover and stand aside for three hours. Then beat in all the flour, add the juice of three oranges, a tablespoonful of cinnamon and half a nutmeg grated; turn into a greased round pan and, when very light, bake in a moderate oven for one hour.

Sweet Potato Pudding.—One quart grated raw sweet potato, one quart milk, three eggs, two cupfuls sugar, piece of butter the size of an egg, one-half teaspoonful of salt, cinnamon and allspice to taste. Mix well, put in a buttered earthen pudding dish, and bake two hours in a moderate oven.

Kentucky Corn Nuts.—To one quart of cornmeal add two teaspoonfuls of baking powder and one teaspoonful of salt; sift twice. Then add enough sweet milk to make a stiff batter that can be molded in the hands. Form into small nut-sized balls, drop into deep hot fat and fry like doughnuts. The balls must be quite small or they will not cook through.

Pistachio Nut Cake.—Cream one cupful of sugar and one-half cupful of uncolored butter together until very light; add half a cupful of milk, sift 1½ cup of flour; use the pastry flour for all white cakes; reserve one tablespoonful of this to mix with the baking powder, and sift the rest into the mixing bowl and beat with a wooden spoon for five minutes. Now stir in lightly the whites of five eggs beaten very light and add last of all one teaspoonful of baking powder sifted through the tablespoonful of flour which was reserved for that purpose; flavor with half teaspoonful of pistachio extract. Line a square cake pan with well-greased paper, pour in the batter and cook 40 minutes in a moderate oven. The greatest care must be exercised in the baking; do not take it out of the oven too soon or it will fall. When the cake is cool make a boiled icing with one cupful of sugar cooked until the stringing point, poured over the white of an egg beaten well meanwhile and flavored with pistachio extract. Chop very fine one ounce of pistachio nuts, spread them over the cake and spread the icing on top.

Beware of Them

There are two afflictions which perhaps give the most pain and trouble, viz:

Sciatica

and

Lumbago

Both disable and cripple, but

St. Jacobs Oil

is their best cure.

Corns that ache quickly removed by A-CORN SALVE. Trial box free. Giant Chemical Co., Philadelphia

Free for a Club of Four.

Here are 44 first-class tools for repairing shoes, rubber, harness and tinware. We are going to give no arguments why you should have them. The reasons and uses are apparent to every one. There is nothing like mending a hole, putting in a stitch, or driving a nail in time. It

always saves time and money. It often saves lives. The price is $2 alone, but it need cost you only $1. Send us one new subscription with $1, and $1 extra—($2 in all) and we will send you the outfit complete, or we will send it to you free for a club of four yearly subscriptions at $1 each

van Houten's Cocoa

combines Strength, Purity and Solubility. A breakfast-cupful of this delicious Cocoa costs less than one cent.

Sold at all grocery stores—order it next time.

Publisher's Desk.

To January 1, 1902, for 50 Cents.

During the last two years we have received several thousand letters thanking us for the new rose, Ruby Queen, most of them saying at the same time that the writers are always glad to do a good turn for THE R. N.-Y. We are going to give these good friends a chance now to interest their neighbors in the paper. We have some roses yet left. Get two of your neighbors to give you 50 cents each, send us the dollar and their names and addresses. We will send them the paper the remainder of this year, and each a rose by return mail. For your part we will send you postpaid Mr. Stringfellow's New Horticulture, which is advertised in another column, for 50 cents. We hope to hear from several thousands of our friends on this proposition. Do not put it off. See what you can do at once. As is well known, we never make any great promises as to what is to be printed in THE R. N.-Y. We like performance better, but we have matter now in hand and in sight which will surely prove strong and readable. From now until January 1, 1902, for 50 cents is a great bargain. Mr. Stringfellow's book is easily worth $1 to any man.

BUSINESS BITS.

MOORE BROS., Albany, N. Y., are practicing veterinarians. They offer the "Best Gall Cure on Earth" and other veterinary remedies to THE R. N.-Y.'s readers.

"HORSE TROUBLES" is the title of a booklet issued by the Newton Horse Remedy Co., Toledo, O. Heaves, distemper and indigestion are the troubles given special consideration. The booklet is free for the asking.

THE Hapgood Plow Co., Box 334, Alton, Ill., offers "the greatest bargain on earth" in the buggy line. Their advertisement gives full description of the buggy, and tells how it is possible for them to sell this buggy so cheaply.

THE Duplex ball-bearing woven wire fence machine is said to make 100 different styles of fence, and the manufacturers conservatively estimate from 40 to 60 rods of farm fence a day. Kitzelman Bros., Muncie, Ind., are the manufacturers of this machine, and they also make a large line of ornamental fence and gates. Write for printed matter which will show the different designs of fence and prices of fence machine, etc.

THE famous musical Swiss cow bells are made in sets of three bells, and are accurately tuned to accord. If three or more cows of a herd are wearing these bells the effect is a beautiful and musical chime. Bells are made in sizes four, five and 6½ inches in diameter, and fitted with handsome russet straps and buckle. Bells can be bought in sets or separately as desired. Send to Bevin Bros., East Hampton, Conn., for circulars, prices, etc.

CHICAGO has long been the leading metropolis of the West, and now the great inland city bids fair to become the London of America—the great warehouse of the world's commercial activities. On April 22 the steamship Northwestern, carrying a cargo of McCormick machines, cleared from the port of Chicago bound for Liverpool, England. This vessel is the first to go from the great manufacturing center of the West direct to Europe. Following the steamer Northwestern the Northman, also carrying a cargo of McCormick machines, cleared from the McCormick docks April 24 bound for Hamburg, Germany. The cargoes of the two vessels comprised more than 144 carloads of McCormick machines, mostly self-binders and mowers. In making this initial shipment by an all-water route direct to Europe the McCormick Harvesting Machine Company has made Chicago a seaport and established a line of freighters that during six months of the year will ply regularly between the Lake City and European ports.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

However bad the Cough, relief will come through a judicious use of Dr. D. Jayne's Expectorant and in the great majority of cases, a permanent cure will follow.—*Adv*

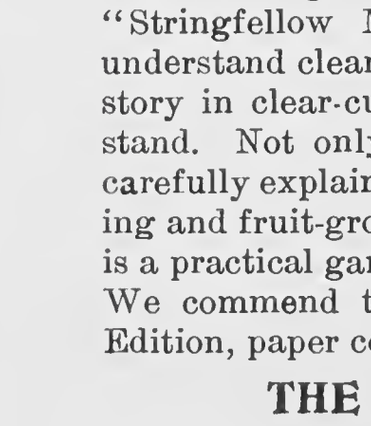
WANTED.
FRUITS, VEGETABLES, HOTHOUSE PRODUCTS, FANCY EGGS, POULTRY, Etc. We solicit your consignments, and can secure highest prices for prime goods. Write us for shipping instructions, stating what you have for sale.
ARCHDEACON & CO., 100 Murray St., New York

Other farm implements are used only in one kind of work and in one crop during the year, but our *Handy Wagon* saves you money and labor every day. Good on side-hill or flats. It is handy, cheap, durable, and leaves no tracks in the fields. Catalogue free.

FARMERS' HANDY WAGON CO., Saginaw, Michigan.



BIG DRESS GOODS OFFER.

For $1.99 we furnish a FULL DRESS PATTERN of seven yards of genuine NORTON FANCY BLACK MERCERIZED CREPON DRESS GOODS, regular value, $5.00.

SEND NO MONEY. Cut this ad. out (No. 150L) and send to us and we will send you a big full dress pattern of seven yards of this fine, new style dress goods by express C.O.D., subject to examination. You can examine the goods at your express office, and if found perfectly satisfactory, exactly as represented, such a dress pattern as you could not buy from your storekeeper at home at less than $5.00, a class of goods that is seldom found in country stores at any price, pronounced by everyone the greatest value ever shown in your section, then pay the express agent OUR SPECIAL OFFER PRICE, **$1.99** and express charges. Express charges will average from 25 to 50 cents. By ordering two or more dress patterns at once the charges per pattern will be much reduced. If more than seven yards are wanted, 36 cents per yard extra.

THIS IS A GENUINE NORTON BLACK MERCERIZED CREPON DRESS GOODS an elegant strictly up-to-date fabric for suits or skirts, good weight for year around wear, a firm cloth we can guarantee for service, fancy raised crepon effect, goods that we have bought direct from one of the largest mills under a positive guarantee for quality.

OUR SPECIAL $1.99 PRICE for seven yards of this 38-inch goods (a full dress pattern), is a price based on the actual cost to produce, is less than dealers can buy in 100 piece lots, is such value as was never before offered by any house. We make this heretofore unheard of offer of $1.99 for a full 7-yard dress pattern to advertise our Dress Goods Department, and get people everywhere to send for catalogue. Write for free Dry Goods Catalogue. ORDER TODAY! DON'T DELAY! When these goods are gone they never again can be offered at the price. Order two, four or six dress patterns at our special $1.99 price, by getting your friends to order with you, and in this way the express charges per each one will be almost nothing. Address **SEARS, ROEBUCK & CO., CHICAGO, ILL.**

The New Horticulture

BY H. M. STRINGFELLOW.

We do not hesitate to say that this is one of the most interesting books on horticulture that ever was printed. Most reading farmers have heard of the now famous "Stringfellow Method" of planting trees, but few understand clearly what it is. This book tells the whole story in clear-cut, forcible style, which all can understand. Not only is the theory of close root-pruning carefully explained, but the general principles of gardening and fruit-growing are discussed. Mr. Stringfellow is a practical gardener, and he gives his own experience. We commend the book to all without reserve. New Edition, paper covers, 50 cents.

THE RURAL NEW-YORKER, New York.

Market Briefs

PICKED UP HERE AND THERE

RETAIL FRUIT TRADE.—It is surprising to what an extent the Italians and Greeks have captured the retail fruit business of this city. Formerly butchers and grocers handled this almost exclusively in the up-town districts, but now many of these rent a window or corner of the store to an Italian, who takes to this fruit trade as naturally as a duck to a millpond. The butcher or grocer thus finds that he can satisfy his customers and get more out of it in the long run than by handling the fruit himself. How can the Italian afford to do it? Simply because it does not cost him much to live and he is willing to work for almost nothing.

DIGGING UNDER DIFFICULTIES.—New York streets are always more or less torn up by the street car companies or the gas or water works, but at present the whole city is suffering from a "breaking out" almost equal to smallpox. The cause is the work being done on the underground railway. It would be quite a task to dig a ditch of this size in the open country where there is clear sailing and plenty of room to put the earth that is removed; but as soon as one gets below the pavement here a regular tangle of gas and water pipes and bottled-up electric wires is struck, and supports have to be made for these from the surface, while the digging underneath them is done. Also, there is no room in many places to put the earth, and it must be carted away as fast as removed. Anyone with a desire to study the methods of engineers in handling a big job of this sort will find an unusually good opportunity in this city at present. Generally operations of this kind are so hidden by high fences that the public has no chance to see them, but there are so many sections of the city where this work is going on that there is no trouble in finding some out-of-the-way corner where one can stand and look as long as he likes. The new bridge across the East River is also an interesting thing at present, as the work of laying the new cables is under way. Many visitors to New York take in the theaters, museums and walk a short distance along the Bowery, and think that they have seen it all, practically ignoring the great and constantly changing produce markets and building operations.

THE SHARKS who make their living by swindling farmers who send them produce for sale are unusually active at two seasons of the year, viz.: just before the holidays and in early Summer. They know that at those times farmers have considerable stuff for sale, and so they send thousands of circulars throughout the country, making the most extravagant promises in regard to the prices they can get and the tremendous facilities they have for selling stuff. People are more suspicious of these sealawags than formerly; still some seem to think that the liars all perished in the Flood, and that no new crop has come up; that whatever a man promises he must mean to do it, or he would not promise it. Of late we have had inquiries asking us to look up this or that commission man. This is the best evidence that we know of that the scoundrels are at work with their circulars bidding for the farmers' early fruit and vegetables. In nearly every case the name is one that we are not familiar with, and going to the number given, the party is found occupying part of a store. There is a small movable sign which can be hooked on a couple of nails beside the door or on one corner of the building. Nearly all inquiries that we have are about people of this kind rather than old-established firms. Are they reliable? Who can tell? They may be, to all appearances, doing a square business to-day and "bust" the next. We know of men who have done business in a little corner of another man's store for years, and who are as "straight as a string," yet so little capital and plant are required to do business in this way that rascals have an unusual chance. The only sure way that we know of to find out whether one of these men is honest or not is to try him, but this is too much like the famous method of learning the difference between mushrooms and toadstools—by eating them—to suit most people. Why do people inquire about these toadstool business men rather than those who stay in one place year after year? Because the latter know that they must not make promises that they cannot carry out if they expect to stay in business. The other fellows don't expect to stay any length of time in one place. The only general rule that can be given is to be cautious in taking hold of any of this tempting bait of promised high prices, even though it may be unjust to some who really have a trade by which they can dispose of certain products at an unusual figure. Another thing that has been mentioned before, but which it is well to keep in mind, is that when one gets hold of a commission merchant who uses him right, it is a good plan to stick to him, even though there may be times when he sells your stuff for less than your neighbor gets. The chances are that you will come out best in the long run. W. W. H.

BRIARCLIFF AGRICULTURAL SCHOOL

A Formal Opening.

The formal opening of the new dormitory, lecture-room, and office building of the School of Practical Agriculture and Horticulture, Briarcliff Manor, N. Y., took place May 15. Last September this school was opened in temporary quarters with 10 students. There are now 30. The new building stands on high ground overlooking a large share of the 6,000 acres of dairy and fruit farms owned by Walter W. Law. Speeches were made by trustees and others interested in the school. R. Fulton Cutting said that the great business of civilization should be to give every man, woman and child a chance for the development of the best that is in them. He spoke of the way in which the unskilled laborer is handicapped, and of the hopeless struggle of mere muscle against brain and muscle intelligently used. He said that the competitive system would be entirely wrong if provisions were not made to give every one a chance to develop himself so as not to be put at a disadvantage in the struggle for position. Hon. James Wood spoke of the need of more intelligent methods in farming. He stated that agriculture in this country is carried on in the most ignorant method of any country in the world—the method of depletion. We feel proud of the resources of this country which enable us to send vast quantities of produce abroad; but we fail to realize that these are simply drafts made upon the land, and that no provision is being made for their payment. It is just taking from the soil what has been stored up by nature in the centuries of the past, and giving no return. He emphasized particularly the way in which this is being done in the West, and thought that with our growing population and constant depletion of the soil, the time would come when the balance of production and consumption will be reached; when we can no longer feed the other nations of the earth; when people will have to return to the worn-out lands in the East, build them up and cultivate carefully as is done in the thickly-settled parts of the old world. He thought that any movement that would show people more intelligent methods of handling the soil should be encouraged, and that instruction in this matter could be summed up in two points, first showing how the fertility in the soil may be conserved and increased, and next how it can be taken out to best advantage. It is the law of putting money into the bank and drawing it out when needed. He said that in all work the two great necessities were "know how and can do, and that in the lives of many men there is a chasm between these two points in to which they fall and never escape from it. Mr. Law spoke of the work that was being done on Briarcliff Farms. He said that their aim was thoroughness—to do everything as well as could be done, and mentioned the motto which is tacked up in their buildings:

"Though only a cobbler, I'll make it my pride the best of all cobblers to be;
"Though only a tinker, no tinker on earth shall mend an old kettle like me."

Dr. Felix Adler, who is well known for his interest in education in all lines, and manual training in particular, spoke of the two widely different types of men, those who live by their wits and those who live by their muscles alone. He believed that the combination of wits and work made the man who gets the most out of life for himself and does the most for others. He said that a school of agriculture, particularly for the Summer, was needed by those who attend the manual training schools in the city. Dr. Adler is the head of the Society for Ethical Culture. He said that he recently received a letter addressed to him as president of the Agricultural Society of New York. He considered it a compliment, as it seemed to him that agriculture and ethical culture are not at all opposed to each other. "We all need to be cultivated," said he, "and the best and only way to cultivate one's self is to cultivate something else. It is not done by sitting down and saying 'I must do this and that and thus cultivate myself,' but by helping to improve some other person or thing the miracle happens that we ourselves are helped, and in no other way."

Director Powell spoke of the methods and aims of the school, which are in brief to enable young men and women to study intelligently the soil and its products, how best to improve lands, and to learn the various kinds of farm work by actual experience. He was encouraged by the interest the students show in their work. Thus far nine-tenths of them have been from the city, young men and women who are anxious to get out of city life and learn how to handle farm lands. Some of them are people of means who are looking to farm lands as investments, and wish to become familiar with the best modes of farming. Mr. Van Norden, president of the board of trustees, stated that the running expenses of the school were about $12,000 per year, and that at present the fees from students pay about one-third of this amount, the remainder being met by voluntary contributions. A Summer course in nature study for a month beginning the middle of July, has been arranged, particularly for public school teachers who wish to do a little vacation work in this line. The outlook for this school is promising, and it is certainly deserving of the support and patronage of those who believe in the spread of practical agricultural education in a business-like method.

W. W. H.

The season here has been favorable to all kinds of fruit. Peaches, plums, pears and cherries set full crops. Apples bloomed very freely, but it is too early yet to tell how they will set. Strawberries are in full bloom now; weather cool and dry. Gardens all late; condition of wheat extra good.

Barborsville, Va. A. R. L.

SILAGE AND HORSES.—Is silage ever fed to horses? E. E. G.

Purdy's, N. Y.

Not usually. Cases of such feeding are reported from the South, but some deaths in horses have been traced to the silo. At the North but little silage is fed to horses or mules—the general opinion seems to be against it.

Live Stock and Dairy

THE BREEDER'S WAYSIDE.

Pasture with Rape.

1. I am thinking of sowing rape in corn at last plowing about July 4, cutting the corn off for fodder, then pasturing the rape. Will the rape make a good Fall pasture for cows? Is there anything better to plant in cornfield for Fall pasture for dairy cows? Can corn be cut late enough for fodder and not diminish the quality or quantity of corn? 2. Do you know of any solution in which to dip eggs to keep them fertile from late Summer until Winter? D. S.

Savoy, Ill.

1. Rape is a plant with a very succulent leaf, and with a rather strong flavor of the turnip or cabbage type. Consequently it is not recommended for dairy cows, neither do I know of its having been used in this capacity. Furthermore, unless fed with extreme caution, hoven or bloat would be likely to occur. So I would not recommend this plant for dairy cattle. The desire seems to be to secure a late Fall pasture. If rye were sown late in August or early in September this result might be secured, and fair grazing be available in late October and November on fertile Illinois land. Then this same land could be pastured some the following Spring. Dairy cows being milked, however, should only be pastured on rye for a few hours (two or three) *right after milking*, and not all day, otherwise the milk will have an undesirable flavor from the rye. Rye can be safely pastured if the cows are turned on as above specified. Corn in central Illinois should be suitable for soiling purposes till late in September without serious fear of frost. Then rye could follow this. Corn produces a most excellent soiling crop, and rye could be drilled into that part of a field from which the corn had been cut off, and thus the green food be well carried into the Fall.

2. The fertility of eggs cannot be maintained for any extended period of time. The egg, however, may be kept fairly fresh by placing in lime solution or painting it over with hot paraffin, but this has no special application to the matter of fertility. C. S. PLUMB.

That Kicking Cow.

I am much interested in your statements about the kicker. I won't be surprised if your pet theories are jarred a bit when old Jersey's heifers come to pail. One favorite with me is a breeching to prevent the cow from backing, a strong hame strap twice around ankle with chain out behind low down. Cow can kick at will, and cannot hurt you but does jar herself. E. L. S.

Barnstable Co., Mass.

As to that kicking Julia, never sell a cow because she is a kicker. When about 12 years old I took my first lessons in milking, and the cow that I then tried to milk would kick me clear across the stable. I never succeeded in doing much with that cow, but since that time I have milked many kickers and owned several, and I say if the cow is in all other respects a good animal I would not dispose of her because she would kick. F. H.

Plymouth Co., Mass.

The Hope Farm man tells us of a cow he has that is a confirmed kicker, and says it is his intention to have her made into beef because of that bad habit. My neighbor remarks that a kicker can be milked with comparative ease by putting her in a stanchion and laying some stout poles alongside of her, and milking through the bars. If she kicks then "she hurts nobody and nothin' but her own self," and if not too confirmed in her evil way may be cured by this method. J. Y. P.

R. N.-Y.—We have a plan like this for milking Julia. A stout frame, hinged like a door, swings up against her and fastens so that she is crowded up tight and cannot make a long kick.

I would like to suggest another cure for the Hope Farm man's kicking cow. I think I could milk her. I would get a small pail with a funnel-shaped cover with a small hole in center for the milk to pass through, and a chair high enough so that the cow could not turn toward me and tip me over; I would hitch her in stanchions near the wall, so that I could stand her alongside of the wall, put a halter on and hitch it in front so she could not go forth or back. I would sit down with my leg in front of the cow's leg, the nearer the top the better, and under far enough so that she couldn't kick by; lean against the cow and if she tries to kick with the opposite foot give her a little push. If she tries to kick with foot next to you raise your knee as high as possible and hold her leg back. I have milked heifers this way that had never been milked before, and when the teats were covered with sores. I would keep the teats covered with vaseline. I think it makes the teats tender to let the calves suck. There is nothing that will make her give up so quick as to find that you can hold her by main force. E.

Montpelier, Vt.

What Makes the Cream Bitter?

For six years I have made good butter, so that those who bought it preferred it to creamery, but for some reason I cannot do it now. Some of the time I have had one cow (a good one), sometimes two. Along in the early Winter the milk, or rather cream, began to be bitter (only one cow then), but the milk was perfectly good. I had for all those six years let milk stand 48 hours before skimming, but for some time now have let it stand but 36 hours, though I cannot see that it makes any difference. I churn twice a week, wash in three or four waters, or until clear of buttermilk; salt, work, let stand a few hours, then work again, and put in pound prints. I churn but twice a week, as that is as often as I can go to market. The cow has good Alfalfa for hay, and has always had bran once a day until within a month, I changed that to cornmeal, thinking that might make a difference, but it does not. She eats well, seems well, although she does not chew as much as the young heifers do. She has good water to drink. As I said, the cream is bitter, not bad. Sometimes I do not deteet any bitter taste, but the butter is not really good, and in a day or two is strong. If I had not made good butter all these years, and done exactly as I am doing now in every particular, I should think I did not know how. The milk is kept in the same place and treated all the way through as it always has been. The cow has been giving milk since last June; will be fresh next August. Two months ago a heifer calved and now I have her milk, but it is no better. I am particular to have everything clean; never use the milk pans for anything else, and I cannot imagine what the trouble is. H. T.

Mesa, Col.

From the statement given I should say the trouble is a bacteriological one. There are species of bacteria that cause a bitter taste in milk and cream as a result of the decomposition of the casein. These bacteria produce endospores; that is, they take on a form that is very resistant to changes detrimental to the life of the germ. Hence, they are not easily killed by heat; in fact, they are often found in boiled milk, the boiling having killed the lactic acid germs, and left the conditions favorable for the troublesome forms. Your utensils or dairy room may have become seeded in some way with the bacteria that cause bitter flavors. If this is so, they are probably present in considerable numbers even in the dust of the room. Your dairy being small, you probably do not have access to live steam to sterilize your utensils, and no matter how carefully you may clean and scour, it is almost impossible to kill all bacteria without sterilization. If, as I have supposed, live steam is not available, submerge all utensils in boiling water and keep the water boiling for half an hour, then put them in the sun and repeat in eight or 10 hours. Be sure that no pans, cans or pails are overlooked, and keep it up for two or three days. It is perhaps unnecessary to add that care should be taken to keep all dust out of the milk and cream. If this does not remedy the trouble I should recommend you to correspond with your State Experiment Station at Fort Collins.

J. A. F.

Seeding Alfalfa.

My experience and the general experience of the farmers of Onondaga County does not agree with Prof. Voorhees on the amount of seed required to seed an acre. We find 10 pounds enough, and several have succeeded with less. The larger amount makes the plants so thick that they do not get sufficient root to prevent heaving the first Winter. If 10 pounds fail 30 certainly would on the same ground. Canada experimental farms have made a thorough test on plots with different amounts of seed per acre. The growth of top and roots was weighed carefully. They found that amount gave the best results. A variation either way from that amount resulted in a diminished yield, 14 pounds not yielding more than seven pounds. He claims its main value is as a forage for soiling. Fifteen years' experience has taught us its greatest value is for hay. It is becoming quite a general practice here to sow four quarts of Timothy with the 10 pounds of Alfalfa. This helps in curing, as the Timothy dries quickly and helps to prevent molding. The quality of hay, especially for horses, is better than the best Timothy; horses and cattle will thrive on this hay with half of the grain required with Timothy hay. CHAS. MILLS.

Onondaga Co., N. Y.

ROOTING HOGS.—To prevent hogs rooting I use the large ring that goes through the nose, one end inserted in an eye at the other end, and have no trouble. With plenty of charcoal or cinders kept by the hogs they will have little tendency to root. These furnish the *roughness* that the hogs get by rooting. Some breeders divide the snout with a knife cutting straight down for an inch or through the rooting tuft; this is very effective. I would advise your readers to use plenty of charcoal or cinders from railroad or some factory; they will not only prevent rooting but will aid digestion. F. F. MOORE.

Rochester, Ind.

DAIRY AND FARM NOTES.

COW DYSPEPSIA!—Did you ever hear of it? Well, feed your cows liberally when you feel like it, and reduce the feed when you feel otherwise; follow the system with these alternating periods of feasting and fasting and indigestion surely follows.

HARSH MILKING!—I am inclined to think much teat trouble comes from harsh milking. Living in the Black River Valley we are on the border of the lumber district, hence get many men who work in the woods at times. These men are frequently poor milkers—not slow milkers. They milk too fast. Nine farmers out of 10 judge one's milking ability by rapidity. I formerly did so myself, but I think otherwise now. These men would milk as one would handle logs. The milking machinery is a delicate system. These often exceedingly sensitive membranes must be manipulated 600 times a year. Is it any wonder we have bunches in teats, contagious garget, swelled udders, etc.?

SLOWER WORK.—My experience and observation is that men who are active, hustling, nervous fellows, who by the way make things *go*, have more teat and udder trouble than the easy, happy-go-lucky farmer, who takes his time in milking as he does in everything else; milks nine cows instead of 12 in an hour. Is this to be construed as an argument against activity? No, but a lesson can be drawn. Learn conservation of energy. We talk about conservation of soil moisture, but it is of far less value: often a fellow can do more hustling sitting still than in his most rapid movements. I think that milking is one of the places where this notion can be safely applied. I do not mean that the slow, indifferent milker is necessarily a good one. It is the man who milks just as the cow wants to be milked. I have sat down and milked many times when the cow would step and step—not a kicking cow; I thought then it was cussedness on her part. There might have been a vein of evil in her make-up, but I am willing to own up that I was milking that cow too fast, or, putting it another way—trying through each pressure of the hand entirely to exhaust every drop of milk that came into the teat. She did not like such close pressure. If I had used one minute more at each milking it would have been time well spent. Some men are very strong in the hands, and do not realize how hard they squeeze when milking.

WOMEN MILKERS.—Women are better milkers than men on account of their delicate touch. This last idea brings to mind the dairy work of a Wisconsin woman, Mrs. Addie F. Howie, of Elm Grove, whose reputation is established in her own State and is now spreading abroad. I listened every day for four weeks to her talks on dairy subjects, which, to say the least, were fascinating. She told in a modest, womanly way of her methods of breeding and feeding her "business partners." I was impressed particularly with a point she made in favor of women managing dairy farms; that they could more fully appreciate the wants and needs of this delicate machine, dealing as we are in her maternal functions. Upon reflection, can you not remember when Mother's suggestion has saved the loss of a valuable cow? I have heard Henry Van Dreser many times credit his mother with the remedial suggestions he was giving. Yes, after all, it was Mother who knew how to do pretty near everything, as every good honest man will testify. I do not believe it makes much difference how the teats are milked, provided only that gentleness is used in manipulation. Of course every one understands that regularity and no change of milkers is always orthodox.

ALFALFA NOTES.—Our Alfalfa has come through the Winter in fine condition, and at present writing, May 13, it is a foot high; pretty good! I have never grown a crop that has presented so many phases of character. It required a long time to learn how to grow it in our climate, and I am not sure of my position yet. Wherever it will thrive the protein question is solved. It must have a rich soil, well fed, free from a hard, stiff hardpan subsoil. The rock must not be too close, as it is in many places in the lime-rock sections. I am bound to stick to it, and win, if possible, having declared in favor of making the farms produce more protein.

CORN PLANTING.—For the past two years we have planted our silage corn thicker, 12 quarts to the acre, and we shall repeat it again this year. The change has reduced the ear growth; 50 to 75 bushels of ears to the acre seems to be about right. It is impossible to find a kernel in the manure. With 100 bushels to the acre we often found whole kernels in the droppings. We are planting our corn later than was formerly considered prudent. The results briefly told, are that land which has been worked frequently for four weeks and planted from May 20 to June 1 gives a more rapid growth, with fully as early maturity. Cultivating a stiff sod is much more cheaply done with three or four horses with a heavy harrow than with light tools or hoes. The latter is simply out of the question if profit is considered.

H. E. COOK.

THE MILK SITUATION.

The Five States Milk Producers' Association was organized in March, 1898, for the avowed purpose of securing a living price for milk. For the 10 years preceding the price as fixed by the New York Consolidated Milk Exchange had gone down, down, until the average monthly price for the year 1897 was 2.34 cents a quart delivered in Jersey City. For the year 1900 the average monthly price per quart was 2.74 cents, an advance of four-tenths of a cent per quart secured beyond a doubt by the efforts of the F.S.M.P.A., for the quantity of milk produced has increased sufficiently from year to year not only to supply the increased consumption, but to continue the "surplus" which the Exchange is constantly struggling to keep down, urging its existence as the reason for reducing the price of milk. This means an advance of $500,000 annually to the milk producers supplying New York on upward of 30,000 cans daily furnished. It is found that the local sections owning or controlling their shipping stations are receiving the best prices for milk. At Tully, N. Y., about 50 milk producers withdrew from the New York shipper and built a plant for themselves and commenced cheese making, selling milk in New York only when they could obtain a satisfactory price. In 18 months after taking the business in their own hands they received $7,000 more for their product than they would had they continued to furnish the New York dealers at Exchange prices as formerly.

The milk from about 1,000 cows is delivered in Owego, N. Y., either to be shipped or manufactured into butter. The milk has been sold up to this time at Exchange prices. A stock company has been formed this Spring, a plant erected, equipped and rented to a shipper at a price that makes it a paying investment. The shipper also contracts to pay the producers for all the milk they desire to furnish him, 17 cents per can above Exchange prices at which they formerly sold their milk; also 17 cents a can more than adjoining stations controlled by New York dealers are now receiving. When this arrangement went into effect the New York dealer they had been furnishing lost all fear of the "surplus" and offered to pay, and is paying, the advanced price. Of course the butter factory, allowing for the milk returned, must pay the same price. Allowing the usual estimate of five quarts of milk annual daily average per cow would make Owego's production 125 cans daily. Seventeen cents a can advance above Exchange prices now being received is equivalent to $21.25 a day, or $3,888.75 for the six months from April to October. Assuming the advance of the Exchange price of four-tenths of a cent a quart for the year 1900 over that of 1897 to continue for the next six months would give Owego producers $20 a day, or $3,660 for the time mentioned more than they were receiving for the same quantity of milk in 1897, making in the aggregate $7,548.75. No close observer doubts that these results have been achieved by the efforts of the F. S. M. P. A. The Association is urging the local sections to secure control of their several stations, about 40 having been secured during the past year, and when a sufficient number has complied it will be able to dictate the price for all.

Campville, N. Y. JOHN J. BELKNAP.

A GOOD GUERNSEY.—The cow shown at Fig. 149, page 371, is Auricula II., No. 12209. With her first calf she milked 40 pounds per day, and promises to give a yet better account of herself as she grows older. She is one of the good ones at Pinehurst Farm, Moorestown, N. J., where E. R. Strawbridge is building up a herd of large producers.

SMALL COWS.—My brother and I are breeding a family of Jerseys that are called low-down Jerseys. I do not know their history, and they may be descendants of the Venango Co., Pa., Creepers mentioned by E. D. H., on page 256. They are small cattle with very short legs, and stout, well-proportioned bodies; good milkers and give very rich milk. They are in demand here by town people who keep but one cow. They are not eligible to Jersey registry, but I suppose we could trace their history if it were worth while. R. H. L.

SOME FACTS ABOUT THE USE OF BORDEAUX

WHY IT IS USED.

When and How Spraying Is Done.

The accompanying illustrations, Figs. 155 and 156, show the two general types of spraying apparatus for Bordeaux as well as other spraying mixtures. Fig. 155 is the style of pump and wagon used in most orchards where, in order to spray the foliage thoroughly, it is necessary to reach a considerable height. It is usually manipulated by three men, one driving and pumping, and the others directing the nozzles from the tower. The tank holds several hundred gallons of the spraying mixture, which is kept stirred up by an automatic device. Consequently, it is an advantage to use a circular tank rather than a square one, as in the former there are no corners for the solids to accumulate. For orchards of smaller trees, such as peach or pear, the spraying apparatus is frequently carried on a low wagon or a stone boat, and for still smaller fruits and shrubbery a device such as Fig. 156 is commonly used. In the use of this one man performs the whole operation. A still simpler device is the knapsack tank and pump, but this necessitates a too frequent renewal of the spraying mixture.

While much has been said about the use of Bordeaux Mixture as a fungicide, and while it is used almost universally among fruit growers, many are still ignorant of its practical importance or of its use in specific cases. The reason for this is probably due to the obscurity of its results as compared with those of insecticides such as Paris-green or London purple. In the use of these one can see the dead insects before him as a proof of the efficiency of the spray, while in the use of the fungicide no fungus enemy may appear, and the fruit grower is uncertain whether its disappearance is due to natural causes or the application of his remedy. Bordeaux Mixture being, like all other fungicides, a preventive, and in most cases not a cure, it is of the utmost importance that its application be made early before the fungus appears. This is made doubly emphatic when one understands the nature of the fungus attacks. A fungus is a plant parasitic upon other plants of a higher order. It is propagated by spores which are carried about in the air. On coming in contact with the host plant they germinate, sending mycelial threads into the tissue of the plant. Thus, after getting a foothold, it may be impossible to kill the fungus, but as it dies of its own accord each Fall after producing what are known as the Winter spores, the attacks the following Spring may be prevented by using some remedy that will prevent the germination of the spores. It is on this account that promptness in applying Bordeaux is of prime importance. Thoroughness is also a necessity, for if even a part of a leaf is not reached by the fungicide, the fungus may find a foothold on this portion.

Although the time of applying Bordeaux depends upon circumstances—the locality, the condition of the weather, and the kind of plant treated—a general practice may be followed of first spraying just before the fruit buds appear; next, just after the blossoms fall and again about two weeks later. If the season is unusually wet a number of other sprayings should be practiced. Under no conditions should the spray be applied while the plants or trees are blooming, as pollination may be seriously affected.

The proportion of different ingredients in the Bordeaux Mixture should vary according to the time of year applied and the kind of fruit treated. For instance, the solution used early in the season should be strong, consisting of six pounds of copper sulphate, four pounds of quicklime and 50 gallons of water, and later a weaker solution of two pounds of copper sulphate, two pounds of quicklime, and 50 gallons of water should be used. For Japan plums a larger proportion of lime and water, than in the first formula, may be used to advantage. Frequently excellent results are obtained by combining the Bordeaux Mixture in the same spray with an insecticide, such as kerosene emulsion or Paris-green. Thus double results are obtained in but one spraying. Although the Bordeaux Mixture itself is strictly a fungicide, it also prevents, in a few cases, the ravages of insects

WAGON SPRAYER FOR TALL TREES. FIG. 155.

by making the foliage unpleasant for them. This is noticeable in the case of potato vines, which on being sprayed with Bordeaux are freer from the attacks of the flea-beetle than unsprayed vines. The spray gives a similar result when applied to cucumber vines. But unless one is spraying for a fungus enemy in such cases, it would be more economical to use an insecticide. Successful spraying, whether with Bordeaux or any other mixture, is, after all, largely a matter of judgment. The fruit grower himself should best know his own plants and their needs. If he act intelligently, fully understand the value of the different sprays, and follow the general principles applicable to all cases, he cannot fail to be successful in his results.

SMALL SPRAYER FOR SHRUBS. FIG. 156.

A. F. B.

OH, what a rest and grand uplift this good old world see, if tongues would ne'er find fault until they had a remedy!

EVERYBODY'S GARDEN.

INTENSIVE CULTURE FOR CRISP QUALITY.

Some Experience With Blackberry Rust.

PLANT PROTECTORS.—A subscriber asks for more definite instructions in making the plant protectors described in a previous issue. In the directions given on page 322, read, "Bend the strips round," etc., instead of "bind the strips," and the meaning will be clear. Use the heaviest tarred building paper, which may be procured from any hardware dealer; the paper fasteners can be found at any book and stationery store. For tomato plants, cut the material into strips 10x28 inches, bend the strip to form a cylinder, giving one inch lap, and secure with the fasteners as shown in diagram. The fasteners, after being passed through the lap, are easily clinched with the fingers. This will be almost identical in size with the ordinary steel peck measure. Any size desired may be made, and smaller ones especially are very convenient. The covers of the same material should be cut in squares from 1½ to two inches larger than diameter of protector, which in this case would be 11 inches. When placing the protectors over the plants press them into the soil or bank lightly at the base; when so placed, if the covers are sufficiently weighted to hold tightly in place, they will protect against considerable freezing. On pleasant days, removing the covers will give the plants the sunshine and still protect from cold winds, which often chill and whip the plants to their serious detriment.

BEETS.—The late Fall and Winter supply, either for home use or market, are best not sown before June 15 or later, as overgrown stock is undesirable for any purpose except feeding. They will continue growth until late Fall, and the proper time will best be determined by the localities where grown. The best results both as to quality and yield will be obtained by later sowing and depending upon thoroughly enriched soil and intensive culture for crisp quality and desirable size.

PARSNIPS.—The seed is slow to germinate, and if yield is the one object sought, early sowing is essential. For desirable table qualities, however, sow early in June and thin to four inches, and cultivate thoroughly for the growth. Deep, mellow and moderately rich soil will give best results. Avoid fresh manure, as this causes the roots to grow rough and unshapely. The late Winter and Spring supply should remain in the rows where grown until wanted for use.

VIGOROUS GROWTH.—The table qualities of all vegetables depend very largely upon vigorous growth. No vegetable grown under unfavorable conditions will ever reach anything like perfection. So then, for best results conditions should be as nearly right as possible. These conditions, in so far as man is able to control, are good seed, thoroughly prepared seed bed, careful planting and diligent cultivation. With man's part properly attended to, Nature will usually answer for the rest.

CUCUMBERS.—The Japanese variety will be found excellent for small gardens, as the quality is of the best, and little space will be required. They will readily clamber over a slanting trellis, or grow nearly upright by occasionally tying the vines to the slats with coarse twine or strips of cloth. A few hills will supply the family needs nearly the entire season through, if well watered, and care be exercised in avoiding too large a growth of the fruits. By no means allow them to ripen the seeds, as this will soon destroy the vines. The greater part of the main crop will, according to location, be planted from June 1 to the first week in July. They are best planted in hills five feet apart, or they succeed nicely sown in drills on slightly raised ridges six feet apart. A plentiful supply of well-rotted manure should be worked into the hill or drill, and shallow but thorough cultivation continued as

long as the growth of vines permits. To prolong the bearing season care must be exercised in picking, not to injure the vines, and the fruits should be gathered just as rapidly as the size required for the various grades will admit. The chief insect enemy is the striped beetle, and the best preventives are strong vigorous plants, and soil conditions and culture that will promote the most rapid possible growth of the vines. The principal remedies are air-slaked lime, sifted coal ashes, land plaster, equal parts wood ashes and road dust, freely applied in the morning when the plants are wet with dew. Cayenne pepper is also an excellent remedy; but too costly perhaps for general use. Tobacco dust is a good fertilizer as well as insecticide, and may be used to advantage on all vines, except watermelon, to which it is injurious, and will destroy the vines if used in large quantities. Spraying with Bordeaux Mixture is a preventive of disease, and saltpeter and water, an ounce to the gallon, if applied to the hills, will be found a wonderful invigorator to the plants.

BUSH BEANS.—A plentiful supply of the bush beans for family use may be easily grown as second crop, without interference to other vegetables. The varieties are numerous, and by judicious selections as to time of maturing may be safely planted from May 10 up to within 50 days of frost. Planted as they may be between other crops which are maturing in advance of them, a constant supply of snap and shell beans may be had from July 1 to late Fall.

BLACKBERRY RUST.—Personal experience, if successful, may sometimes be worthy of note, even though not following the trend of scientific theory. Two years ago I discovered several plants of blackberries which were badly affected with rust. The plants were immediately dug up and burned, but later on, when the fruit was more than half grown, the disease appeared worse than ever, and began to spread rapidly. All diseased plants were dug and burned, and the remainder of the bushes were thoroughly sprayed with Bordeaux Mixture, full strength, as prepared for Potato beetles. The mixture was the usual formula of 4-6-50 with insecticide of the following formula: White arsenic, one-half pound; sal soda, one pound; boiling water, one gallon, mixed and boiled 30 minutes. This mixture was used in the proportion of 1½ pint to 50 gallons of the Bordeaux. The bushes were thoroughly drenched, and matured a fine crop of berries, as also last year, with no further traces of the rust. The same mixture was twice applied to peach trees which were badly affected with curl leaf, the first application being made on May 30, and the second, one month later. The disease entirely disappeared, and the trees have since borne two crops of peaches without any further appearance of the disease. Doubtless these may not have been thorough tests, or in any way conclusive, but at all events the experiment is worth a trial. J. E. MORSE.

Michigan.

VARIATIONS IN SPRAYING SUBSTANCES.

It is a matter of common knowledge that London purple will remain in suspension longer than will Paris-green, and that solutions which contain the former require comparatively little agitation. This valuable property of the London purple is largely due to the fact that its particles are smaller than those of Paris-green. Again, the London purple, as a finely divided substance, can be spread over a greater surface, and from this standpoint is a more effective poison. Some time ago it occurred to me that some samples or brands of Paris-green, or different samples of any spraying material to be held in suspension, might have smaller particles than others, in which case, of course, the particular lot with the smallest particles would be most valuable for spraying purposes. An examination was made of several brands of Paris-green. The results indicate that the value of this poison, at least, is affected by its state of division.

Pure Paris-green examined under the microscope is found to be composed of small green spheres which are uniform in size in any one sample. But in different samples the sizes of the spheres vary considerably. In five lots examined the average diameter was found to be .0165 millimeter (one-thousandth part of a meter); taken by lots the minimum average was, .0111 millimeter; the maximum, .0218 millimeter. When placed in water in tall glass graduates it could be seen that there was a perceptible difference in the length of time a given quantity of the different lots would remain in suspension.

Soil physicists, who work with sedimentary soils, say that "the theoretical rate of settling of small particles of spherical form in water would be, with the conditions the same, directly as the radii of the particles." That is, that particles twice the diameter of other particles, will settle twice as fast. This law, I think, will apply to Paris-green, and if so, in the cases mentioned above, means that one of the samples examined will remain in suspension nearly twice as long as will another of them. Surely this is a matter of importance to the users of Paris-green. Manufacturers, I am told, can control the fineness of division of the arsenites in manufacturing, and can make a good article in this respect as easily as a poor one. Let the demand be, then, for the small-particled product. To some extent one can judge of the state of division of Paris-green by its color; that having the smallest particles, while of a distinct green, is paler. Experiments may show that the fineness of division may be controlled, somewhat, in the preparation of Bordeaux Mixture and of the now quite commonly used homemade arsenite of lime. U. P. HEDRICK.

Michigan Ag'l. College.

HOG MANURE AND CABBAGE.

As to the use of hog manure for cabbage, our experience has been that it will not do. With us it always caused rot and club-foot, on soils that have been used for cabbage or other garden truck. The only way we ever used hog manure for cabbage with good result was on an old heavy sod. The manure was spread early in the Fall, so that it froze and thawed until Spring. Just before turning the sod over in the Spring we gave the field a liberal coat of lime. Not to our knowledge had the field ever before been planted to cabbage or other vegetables. The lime, of ccurse, kills club-foot, but with us the price of lime is too high at present for general use on farm crops. We were always bothered with club-foot in the hotbed, growing very early cabbage, even where the soil was changed every year, but since we have used lime we have had no trouble in growing two or three crops of plants in the same soil. The soil is usually handled over in the Fall by throwing it out of the beds, and

CHECK-ROW CORN PLANTER AT WORK. FIG. 157.

the lime sprinkled on as it is thrown out. It is left in this way until the beds are made in early Spring.

Chemung Co., N. Y. A. G. MILLER.

GOOD BAIT FOR SUCKERS.

Not long ago a reader in Maine wrote asking advice about investing money. He had received a letter from a man in New York which read as follows (omitting one name of the stock):

Through the sudden death of a large holder of National ——— stock, I have a chance to secure privately a large block of the stock (50,000 shares) at $2 per share. The people who now own the stock must have quick cash. They are firm believers in the great value of National ——— stock, but stern necessity compels them to sacrifice it—they must sell. I cannot at present buy all of this stock, and so will notify a few persons of this rare chance to secure some of it at this great sacrifice of price. There is no other stock for sale under $10 per share, as you will notice by enclosed printed matter. You will do well to buy all of this $2 stock that you can pay for—it is certain to go higher than $10. The price of National ——— stock is $10 per share at the company's office, and, as the people who offer the stock to me at $2 do not wish to interfere in any way with the company's offer of stock at $10, you will please consider this letter strictly confidential. There will soon be an active market established for the stock. You can order through me, and I will buy the stock for you without any charge for commission, because I want to have this cheap stock taken out of the market quickly.

Our friend was impressed by this plausible letter, and evidently felt inclined to invest some of his savings in this stock. Before doing so he was careful to investigate. This letter was really a type-written circular printed so well that most people would be deceived by it. Not even the name of our friend was written in. That stamped it as shaky from the start, for who would send *"strictly confidential"* advice to strangers on a printed page? The same thing was probably mailed to 10,000 names secured at random in the hope that a few would bite at the bait. The man who sent the circulars probably hires desk room in some office. He may have the skeleton of a company, but the shares he offers are not listed on the New York Stock Exchange and are not handled by brokers. Here in this great city are thousands of men hunting for bargains. If shares could be bought at $2 and quickly sold at $10, every one of them would be sold here in 24 hours. The fact that it is necessary to appeal to strangers is good evidence that men who are here, capable of estimating such things, do not consider this stock worth buying. In that case what folly it would be to send money to an entire stranger. It is easy to say this and yet certain country people are doing this again and again. Somehow the idea of becoming a "stockholder" in some bogus or crippled concern appeals to them, and they cannot resist the temptation. Money is taken out of the bank or from the hands of good old friends and sent to the rogues and financial wolves who only sharpen their teeth on the hard-earned and sweat-stained dollars of country people. The above letter is only a sample of many. Strange, is it not, that men will be caught by such an old bait? Sad, is it not, that the money which would bring so much pleasure and comfort to wife, children and home should be fed to sharks?

FREE TREE DISTRIBUTION

It is quite gratifying to learn that our Department of Agriculture purposes to furnish gratis trees for planting. This promises to be a great advance upon seed distribution as practiced. I am wondering whether the Government will furnish these trees without labels, as is done with the seeds this season, being simply designated as of a "select variety." It would look as though farmers were to be regarded as unskilled subordinates, unfit to be entrusted with the names of things. The seeds went promptly into the stove, and a postal card dropped to my representative protesting against such foolishness. So far as my knowledge goes these free seeds have never been helpful to the planter, have brought no useful knowledge back to headquarters following their use, and have had only a future campaign significance. Better use the money in supplying such things as the farmers really need, new acquisitions from foreign parts, and thoroughly advertise among farmers that such are to be had for the asking. The past Winter I applied to the Department of Agriculture for basswood trees or seeds, to learn that such were not forthcoming. The Government will have a large contract on its hands if it meets the demand for trees which I anticipate will come. Are these trees to be "reported upon after trial," as with the seeds? It is apparent that they must be regarded as a direct gift to the recipient. And in giving, why not give the most useful gifts, say fruit trees? A private gift to individuals from the Government is wrong in principle unless it is apparent how the community is to be directly benefited. The people's money must settle the bills, and hence it would seem proper to give trees for street and park planting, but not strictly so for private control, except under the plea of novelties tested. The basswood trees I applied for were intended for planting along streets, subject to State control, and especially calculated to furnish bee food as well as shade. I am pleased that Uncle Sam now sees his way clear to give me these trees. F. W. PROCTOR.

RURAL TELEPHONE LINES.—To get such a line started you must have some one interested enough to get subscriptions from those living along the proposed route, or near it, sufficient to build it, those being most benefited taking two or more shares. Getting started has been the greatest trouble here. Shares are $10 each, which entitles holder to attach telephone to line and free use of same. Each village has a central, with from three to 15 lines coming in from surrounding towns and country, each line giving free use of its own for the same privilege over the other lines. Centrals are supported by assessments on shares, and small sums charged outsiders for use of line. They charge them here 10 to 15 cents per message. In building the line shares are paid for in cash, work or poles. The cost here has been from $35 to $40 per mile. We can talk in almost every village within 20 or 25 miles and most of the business men have telephones. The bridging telephones have given better satisfaction here than the series. They say the metallic circuit gives the best results, but cost is double for wires. F. E. B.

Broome Co., N. Y.

CHERRY CULTURE.—The best sweet cherries I have seen south of central New York are along the fences, where the cultivator has not disturbed them. In northern Delaware there are several famous sweet cherries in the fence rows and corners, but nearly all of the orchards that I have seen in which modern cultivation methods are attempted have been failures. In central and eastern New York the sweet cherry has to be kept on medium thin land. My father has a young orchard that is booming on land that would be considered poor for farming purposes, but the trees respond there to tillage. The sour cherries will probably do best under high culture. While they grow well along the fences, they need more moisture than the sweet varieties, and pay well under the best treatment. The dark kinds are the money makers; Black Tartarian, Black Eagle, Windsor and Dikeman are the leading sorts at home. There is big money in Windsor, and if Dikeman turns out as we expect it, there ought to be more in it. Sometimes the sweet cherry needs lime and dies for want of it. Some kinds need it more than others. Tartarian, I believe, is one of them. [Prof.] G. HAROLD POWELL.

Delaware.

THE HEN AS A MACHINE.

The Requirements for Egg Production.

PART II.

An egg is a complete food and must contain everything necessary to form a complete chick. Mike would be as completely "stuck" if the Deacon failed to furnish him with a match to start his fire as he would be without any sap. Where shall we look for these little things? The hen at liberty looks to every insect, bug or worm which she can find. Aside from an egg, milk is the principal example which we find in nature of a complete food. This is undoubtedly the reason why it pays so well to furnish skim-milk or buttermilk for a hen to drink, instead of water, when it can be secured. I would also like to emphasize the the sentence where I said "If she have *comfortable shelter* and a well-balanced ration." Very much depends upon the "comfortable shelter" as well as upon the other requirements named. As regularly as the seasons come and go the great mass of hens in this climate cease egg production when Winter appears, only to resume when Spring returns, in spite of balanced rations and everything else. Why is this? I believe it is for want of comfortable shelter in a large degree. A hen's system has its limitations. There seems to be a point somewhere between "a perch among the apple blossoms of Spring time, fanned by the Summer breezes" and "clinging to the bare limb in midwinter, with the wintry blast howling about her head," where Nature draws the line between egg production and sterility. This line undoubtedly varies to some extent between different breeds, and also between different individuals of the same breed, but it is there just the same, and must be taken into account by the successful poultryman. The stereotyped advice usually given is to "keep her on the go." "Make her scratch" in order to keep her warm and comfortable. While this is sometimes effective in keeping her warm and comfortable during the hours of daylight, it is wasteful of feed and energy if carried too far, and is often counteracted by compelling her to shiver on her perch in a cold place during the hours of darkness.

A better way is to warm her quarters by day and by night by conserving the heat of the sun's rays, and the heat of the hens' own bodies. This can now be easily accomplished by a proper construction of the house and roosting quarters, and by the use of the ventilating drum. This is constructed on the principle that different metals have a differing power of conducting heat and enables us to draw off the impure air exhaled by the breath, without allowing the heat to escape. By its use a hen can warm her own roosting quarters in a cold room as successfully as a person can warm his own bed in a cold room. I have recently been experimenting a little with them. One was recently put in place in one of my henneries, which are built entirely above ground, of single-board one-inch siding, lined with paper, on an open foundation of loose stones. This morning (March 7) the thermometer stood at zero on the outside, while the hens inside were in a temperature of 42 degrees.

We are apt to pass the little things by in preparing a balanced ration. Only a little silicon, for instance, is needed in the manufacture of an egg. Surely, you say, she can pick up a grain of sand and get that. But Nature has not given to animal life the power to digest and assimilate crude and inorganic matter, whether it be nitrogen, iron or silicon. The power to take up this crude inorganic matter from the soil and combine it into organic forms is only given to vegetable life. Thus it will be seen that the vegetable kingdom acts as a sort of wet nurse for the animal kingdom. We must take this fact into account when we look about for a food supply. Again, some forms of animal life have been specially endowed with the power to convert the coarse forms of vegetable growth into flesh and blood (and milk), while others are specially endowed with power to reconvert this same matter into higher forms of animal life. The study of the subject becomes more and more interesting as we advance along the pathway of scientific and exact knowledge.

We left the pullet where we said that "if certain conditions are provided she will lay all the eggs of which her individual life is capable." As time goes on there are certain instinctive causes which step in and arrest the flow of the life current towards egg production. The first one of these is the propensity to become broody. This is another instinctive effort of life to perpetuate its species. In a state of nature this effort is put forth as soon as her nest is filled with fertile eggs. Under the conditions by which civilized man has surrounded her, this propensity has been largely overcome by feeding, breeding and selection until, in some breeds, it is almost entirely eradicated. This instinctive effort of life to perpetuate its species is only put forth under home-like surroundings. Remove her to new and strange surroundings and the current of life is at once returned to the channel of egg production. As the season for renewing her covering of feathers approaches the current of life along this channel is again arrested. A naked hen would make a poor showing, hovering a clutch of eggs or a brood of chicks. So Nature has again stepped in and provided that the current of life shall be diverted from egg production and turned to feather production. When this has been accomplished the flow of life's current goes back to the production of eggs again. Right here, however, our rigorous Winters are likely to step in, and in the majority of cases, the point between the apple blossoms of Summer and the bare limb and cold blasts of Winter, marking the limit of her system, is passed, compelling her to wait until the wintry blasts have passed, or until man provides the Summer conditions of comfort in some other way before her task of egg production is resumed.

O. W. MAPES.

PLANTING CORN BY MACHINERY.

Every year, as the time for planting corn approaches, we are met by questions as to how corn should be planted for the silo. Where the area to be planted is considerable, or where several farmers can club together and purchase a corn planter, best results will be obtained by using a machine made for the purpose. Where no regular corn planter can be secured, we would plant corn with an ordinary grain drill. These drills are usually made with the drills seven inches apart. By closing five or six of the drill holes the rows may be drilled in 35 inches or 42 inches apart as desired. The mistake should never be made of planting corn too thin. Enough seed should be used on the start to insure a stand. After the corn is well up it may be thinned by harrowing, and the corn which remains will be benefited at the same time. We would set the drill to plant at 42 inches in preference to 35, and then leave the plants a little closer in the row. The harrowing which should be given to thin out the plants will largely do away with the necessity of cultivating both ways, except upon land badly infested with weeds or grass. The accompanying illustration, Fig. 158, shows corn being planted by a machine made to plant in check rows, i. e., rowed both ways. On hilly land the regular check-row arrangement does not work well, and if we wish it rowed both ways the ground must be marked one way beforehand. The machine shown plants two rows at a time, and the grain is dropped in front of the wide wheels, which firm the soil over the seed. These wheel marks show where the corn is planted, and cultivation should always begin before the corn plants show above ground. Planting corn should not be delayed a minute after the land is in proper condition. A delay of half a day may in case of rain mean a delay of a week. A machine for planting corn has become almost a necessity in modern agriculture.

TRUTH OF CATALOGUE ILLUSTRATIONS.

Mr. Allen in a recent and timely article makes a noticeable defense of catalogues charged with exaggeration in illustration. Of course it is admitted that the drawings or photos are usually made from exceptional specimens grown with particular care, and no more represent the average individual product of ordinary seed and culture than a fat ox resembles the common runt cow of the Florida sand barrens. Certainly there have been fictions in this kind of pictures, but it is safe to assert that the actually accomplished results of horticultural and agricultural production have never been adequately portrayed on paper. I remember seeing a picture in colors of part of a strawberry field, in full bearing, and remarked: 'Nice picture, but quite imaginary—impossible—too much red," and since then have grown strawberries that looked like strips of red flannel a foot wide stretched across the field, and people looked at them with unfeigned amazement. Several years ago, when balsams were in vogue, the pictures of them in the catalogues were simply immense. It required lots of faith or credulity to believe them to be within half a mile of the truth. As a trial I grew some with care, planting them in bowl-like depressions in the rich soil, and feeding and watering them well. Keeping off all dead branches I grew them four feet in height, with stems four inches through, covered all round from bottom to top with large double Camellia-shaped flowers measuring 3½ inches across. I was urged to put them in tubs and send them to the American Institute for exhibition. Any attempted illustration of those balsams would have been characterized as an exaggeration. I have before me one foot of wood of Burbank plum, on which I count over 200 blossoms, and the whole tree is as white as snow. If it were possible to make a picture of the tree as it is the representation would be set down as a burlesque on the truth or a first-class whopper! J. YATES PEEK.

THE SEED END OF POTATOES.

The article on this subject in your issue of May 4, by Mr. Boardman, recalls some experiments in this line, made at our Station several years since, and reported in our annual report for 1892. The experiments continued through four years, and in every case the larger yield was secured from the seed potatoes from which the seed end was not removed. I quote the summing up of these experiments:

"It thus appears that in each of the four seasons during which the trial has been conducted, the entire seed has given the larger yield the difference, amounting on the average to something more than 4½ per cent. It is noticeable also, that in but one of the four seasons did the yield of small tubers from the entire seed equal that from the seed having the seed end removed. This fact would appear to disprove the only argument that I have heard advanced in favor of removing the seed end, viz., that the planting of a cluster of eyes at the distal end of the tuber tends to multiply shoots, and thus to increase the percentage of small tubers. The only conclusion warrantable from these trials is that, under the conditions in which they were conducted, the removal of the seed end was detrimental to yield. This result is in accordance with analogy. The potato tuber is not a root, but a thickened underground stem, of which the so-called seed end corresponds to the apex. It is a well recognized fact that the terminal bud of a shoot is the strongest one, and the removal of this bud tends to check the vigor of growth. The seed end of the potato tuber sprouts first in Spring, and when the tuber is planted whole, the first and the strongest shoot almost always proceeds from the seed end. Theoretically the continuous removal of the most vigorous buds would tend to diminish vigor and productiveness."

Your editorial on page 334 has also set me to thinking. You say: "No, my scientific friend, the fact that you publish a good bulletin dealing with some fact or method does not settle the matter for good. Many people will not take the trouble to read it. Many will never know it was published. Some will read and forget it—others will not understand it." And you might have added, some will dispute your testimony when you give it. I have stated the results of the above carefully-conducted experiments at farmers' institutes, and had them contradicted from the audience by men who did not claim to have made any experiments in the same line. After all, are the experimenters all to blame because the farmers are so slow to accept and adopt their teachings?

Wis. Experiment Station. E. S. GOFF.

R. N.-Y.—No. Truth darts like a flash when the way is made ready, but is sometimes slower than cold molasses to make a start.

FIGHTING SQUASH BUG.—Recently a subscriber told how he managed to overcome the ravages of the Squash bug and his practice is commendable, but it might be repugnant to many who are disinclined to overmuch physical exertion, as it requires diligence and perseverance in replanting, dusting with tobacco, etc. Somewhere in print I saw a hint to plant in the hill with the squash and cucumbers, turnip or radish seed, and last year did so, and had comparative freedom from bugs. It is quite possible that last year the Squash bugs were a minus quantity. Anyhow, I would like to inquire whether others have tried the plan, and if successful, would like to know the why and the wherefor. J. Y. P.

Van Deman's Fruit Notes.

ALL SORTS OF QUESTIONS ANSWERED.

Propagating Plums from Sprouts.

E. S. G., Madison, Wis.—What would be the effect of propagating the native plum from sprouts as regards the tendency of the trees grown therefrom to produce sprouts? It has been claimed that the growing of trees from sprouts increased the tendency to sprout, and I would like your opinion on this question with reference to the Americana plum.

ANS.—In my experience with the Americana and other species of plums propagated from sprouts and with the cherry and other fruits, I have never noticed any increase of the tendency to sprout; nor have I noticed a diminution of this characteristic, as a result of propagation by grafting. I do not think a method of propagation has any material effect upon the constitutional peculiarities of a species of plant, at least within the limits of an ordinary lifetime.

Barren Apricots.

J. H. R., Schoolcraft, Mich.—Can you tell me how to get some apricots from my trees? They are from six to eight inches through, are full of blossom every year, but have never ripened a single fruit. Most of them drop before they burst the calyx. A very few hang on until they are as large as a peach-pit and then drop off.

ANS.—The common Plum curculio stings the fruit of almost every apricot tree planted east of the Rocky Mountains, and causes it to drop before it is grown, provided it escapes damage by Spring frosts. In some sections, as for instance, in western New York, there is less of this trouble than elsewhere, and there are some profitable orchards there. But in nearly every case more or less jarring is done to catch the insects before the stinging is done.

Wood Veneer Tree Protectors.

H. B. S., Plymouth, Ill.—Do you advise leaving the veneer tree protectors on tree during Summer, and will they protect trees from borers? They are satisfactory for rabbits. Do you advise using them? Will insects enter at top and lay eggs that make the borer at or near the ground, and would they hatch?

ANS.—The most extensive orchardists using the wood veneer tree wrappers, so far as I have seen, leave them on all the year. They are excellent for the purpose of keeping off rabbits and they also prevent borers to some extent. The eggs of the Round-headed apple-tree borer are usually laid just where the trunk meets the earth, and if the wrapper is pushed well down to the earth there is almost no chance for this insect to lay the eggs where Nature dictates. Very rarely the eggs are laid a foot or more above the ground, especially where the shade is dense, and it is possible that a few may be laid above the wrappers. They are likely to hatch wherever they are laid, for they are slightly inserted in the bark.

Various Orchard Questions.

W. H. R., Springfield, Mo.—1. Will Kieffer pear reproduce itself from seed where no other variety blooms at the same time? 2. Will Richmond cherry succeed budded on Marianna plum roots? 3. What do you think of wood veneer to wrap apple and pears? Here in southern Missouri we are troubled in the Winter with rabbits, and in the Spring with borers; and on pear trees with sunscald in July, August and September, and it looks to me as though we ought to keep the young trees wrapped about all the year. Is there anything better than wood veneer? 4. Will Kieffer seedlings make good stocks to bud or graft Seckel and Duchess on? 5. Will the Lincoln pear succeed here on the Ozark hills, and at what age does it begin to fruit?

ANS.—1. No, the Kieffer pear will not reproduce itself true from seed, nor will any other variety do so. 2. The Richmond cherry will do very well on the Marianna plum as a stock, so some have told me, but I never tried it. 3. Wood veneer is very good for wrappers to prevent injury from rabbits and I do not see any serious objection to it, although I have heard a few persons say that the veneer made a harbor for insect pests. I have never noticed anything of the kind, but on the contrary, I have found them an advantage in keeping borers out of the trees. 4. I have never seen Kieffer pear seedlings used as stocks for other varieties, but I believe they would be good. 5. The Lincoln pear will succeed where other varieties do, and begins to bear at five to 10 years old. It is not of high quality.

Borers in Apple Trees.

L. G. L., Victor, N. Y.—Can you tell me what to do for borers in young apple trees? I set about 45 trees four years ago, and I find that some of the newer varieties, like McIntosh Red, Yellow Transparent, Sutton Beauty and few others are badly hurt by the borers; in fact, some of the trees have already died, and I am obliged to take them out. I find four or five borers in a trunk. The trees have been well cultivated and even spaded around, so that they have had clean culture from the start and have made remarkable growth. I have never had any experience with them, and I would like to know what I shall do to prevent their damage.

ANS.—The first thing to do with apple trees of any age that are affected with borers is carefully and patiently to dig every one of them out as soon as their presence is suggested. There are two common kinds of apple-tree borers. The one that is prevalent in the Eastern States is the Round-headed borer, and does its work at or very near the collar of the tree. The best cheap preventive that I know of is to bind heavy manilla paper about the base of the tree, from an inch or more below the surface of the soil to nearly a foot above it. This should be done when there are no borers in, and usually about the time the buds swell in Spring, so as to prevent the laying of eggs in the bark by the beetles, which work is done mainly during the Spring and early Summer.

Fumigation for Bedbugs.

H. B., South Haven, Mich.—On page 308 you tell how to kill bedbugs. Nothing is said about using the acid more than once. Won't there be another crop of bugs hatching from eggs left, which should be killed later by a second fumigation? If so, how long a time should elapse between the two fumigations?

ANS.—The acid can be used only once. After each fumigation pour out the contents of the jar. It contains potash and is useful as a fertilizer. A second fumigation, about 20 days after the first, will kill many of the later-hatched bugs. In some cases, several fumigations are needed to ensure a thorough job.

Cause and Treatment for Crown Gall.

F. E. H., Bucyrus, Kan.—Is the cause of the disease known as root knot or crown gall in apple and pear trees known, and its remedy or preventive? It is a matter of serious importance to nurserymen in the West.

J. O'B., Red Hill, Va.—Can you tell me anything as to the causes of crown gall or root gall on apple trees? I see specimens occasionally in the nursery, and don't know any remedy.

ANS.—This disease, which is really a fleshy outgrowth of the roots of deciduous fruit trees, has been studied at a number of experiment stations, but no definite conclusions seem to have been reached. The best statement of the disease is given in Bulletin No. 33 of the Arizona Station, at Tucson. What is known as crown gall is a swelling which appears generally at the crown of the root of young trees. As it first appears the gall is of the same color as the sound root. Later a dark color appears, caused by a deposit of dead matter. The galls are generally located upon one side of the root body, and have a softer tissue than that of the root. It is believed by most investigators that crown gall is a contagious disease, the germs of which are carried about in various ways. Some authorities dispute this, claiming that the galls follow some injury to the root; but the general opinion appears to be that the trouble is contagious like other diseases. The disease spreads in various ways. In the West, the chief spread has been from the nursery. In nursery rows the disease spreads rapidly from one small tree to another, and when these trees are sent out and planted, whole orchards are infected. The germs are so small that they are carried by the wind. They are also carried through the soil by the water in drainage, and where orchards are irrigated. Decayed galls and the bark at the surface roots may be broken off in cultivating and scattered in this way. Through carelessness the disease has been widely scattered. One case is mentioned in which trees were dug up, cut into stove wood, and sold throughout the neighborhood. In this way the galls were scattered everywhere, and infected many orchards. The losses from crown gall are considerable. The disease generally works underground, and has been overlooked by most of our growers thus far. Thousands of trees have dwindled and died, or failed to bear fruit for some reason unknown to the fruit grower. In the West especially it is thought that many of these cases of decline and death have been directly due to the work of the crown gall. Many young trees have died outright and broken off just beneath the surface of the ground as the result of the galls, which gradually weakened the stem. Prof. Toumey, formerly of Arizona, says that the majority of diseased trees live on year after year, but make less growth, and produce less and poorer fruit than healthy trees. A tree afflicted with this gall cannot do its best. It is estimated that the annual loss from this disease here is $1,000,000 or more.

So little is known about the disease that no certain remedy has been suggested. The best remedy thus far found has been to cut the galls from the crown of the tree and paint the wound with a paste made of sulphate of copper, sulphate of iron and lime. This is usually effective, although in some cases where the work is not well done, new galls appear at the edges of the wound. The galls that form deep down on the roots are not so destructive as those on the crown of the tree, and if they are removed the tree will be benefited. In Arizona orchards have been kept in good condition by inspecting the trees once a year, cutting off the galls as they appear and painting with the paste above mentioned. Trees in their first or second year suffer more than older ones. If possible, nursery stock free from galls should be obtained. If young trees already having galls upon them be planted, there is not one chance in 100, according to Prof. Toumey, that they will ever come to successful fruitage. A single diseased tree in an orchard will carry the disease all over it. If bundles of trees are received having a few of these galls upon them, the whole should be destroyed, for it will not be safe simply to pick out those that can be seen. In the West this gall disease is getting to be a serious thing, and laws are demanded requiring a rigid inspection, so that nurserymen shall not sell trees bearing galls.

CYCLOPEDIA OF AMERICAN HORTICULTURE, by L. H. Bailey and collaborators. Vol. III.; N to Q. New York, Macmillan & Co. Price $5. The third volume of this monumental and most useful work is even more carefully executed, and much better illustrated, than its predecessors. Many important subjects are included, as the alphabetical order is carried from N to Q. Exhaustive articles on the peach, pear, orange, nectarine and quince come in this volume.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

FOR CHILDREN

Nothing, that comes in a bottle, is more important for children than Scott's emulsion of cod-liver oil.

And "important" means that it keeps them in even health. Whenever they show the least disturbance of even balance of health, it promptly restores them.

It is to be used as a food, whenever their usual food does not quite answer the purpose of food.

We'll send you a little to try, if you like.

The Cornell Reading Course.

Edited by John Craig, Professor of University Extension, and Editor Farmers' Reading Course, Cornell University, Ithaca, N. Y.

Observations by the Way.

It's no wonder that poets have their annual "breaking out" at this season of the year! As I am whisked up and down the fertile valleys of central New York my thoughts don't run so much on Spring poetry as they do on "garden sass," clover fields and green pastures. Grass is king! Verdure everywhere. Hillsides covered with vivid green standing out against the lighter and varied shades of the woodland background. Clover in great luxuriant blankets lies thick on many meadows. Alfalfa too, in central New York is frequently represented by thriving fields. We shall hear less of grass-seeding difficulties this year. The ground is soaked in a way that has not been duplicated for years. The season is somewhat backward, but with the abundant moisture, growth will be correspondingly rapid. What of the prospective fruit crop? Greening, King and Spy are making a fair show of blossoms—quite enough for a good crop of fruit if the fruit is protected. In many localities Baldwins will take a rest—a much needed rest. Still there is quite a sprinkling of white in most orchards. Some trees get into the habit of bearing on one side this year, and on the opposite side the following. The east and west sides usually alternate. I suppose the time will come when fruit growers will master the principles of fruit-bud production so that moderate annual crops will be the rule instead of extraordinary alternate crops. The champ, champ of the pump handle, the hiss of the spray, sometimes mingled with an occasional remark of the nozzle handler are familiar sounds at this time in the fruit counties of Niagara, Orleans, Monroe and Wayne. The evolution of the spray pump in this section would make an interesting story. The power sprayer is coming in. Hand power is too slow and tedious for large apple trees in areas over 20 acres in extent. Steam has been introduced; gasoline and compressed air are coming in. Another step in orchard practice has been taken.

Culture of Muskmelons.

Will you give me some information regarding field culture of muskmelons? How is blight prevented? F. P.
Ontario, N. Y.

This Station has not published anything on the outdoor culture of muskmelons. It is a subject which we have been studying, however, and on which we expect to issue a bulletin this year. The industry has grown to quite important proportions in certain parts of the State. Along the Ridge Road in Niagara and Orleans counties it is rapidly taking its place as one of the leading side lines. When I was in these counties May 3-6, melon growers were just then planting the seed. Many of these men have erected greenhouses for the special purpose of starting the plants. Small wooden, bottomless boxes made of veneer about 2½ inches square are used to start the plants. These boxes are arranged in close order on the bench and an inch of well-rotted manure is packed in the bottoms. They are then filled with a layer of sandy loam packed down by means of a tamper. Four or five seeds are sown on the surface and covered with sifted soil. The boxes are then well soaked with water. In 16 to 20 days the plants are ready for the field. A warm site is essential. Sandy loam gives earlier fruit than the clays. A southern slope is to be preferred. The plants are set about 4x4 feet apart, and cultivated like tomatoes. Some growers practice manuring in hill and others do not. If the soil is in good heart, hill manuring is not necessary. A few growers run the risk of having their crop cut by frost by planting the seed in the open ground soon after May 1. If the site is fairly elevated and the soil is warm and well drained, the results are fairly satisfactory. As a rule, the early melons bring the big prices, and the extra labor of starting the plants in the house is compensated by the larger prices secured in the fore part of the season. The blight which attacks the foliage may be prevented very completely by spraying with Bordeaux Mixture. One of the worst enemies to contend with is the Melon aphis or louse. These are held in check by the use of tobacco water. In applying the tobacco infusion, the operator must take pains to cover the lower surface of the leaves. This cannot be done by the ordinary spraying method, but requires special effort.

Spraying; Danger of Poisoning the Pasture.

Do you consider it neeessary to keep calves out of an orchard while spraying? If so, for how long? C. G.
Washingtonville, N. Y.

If you are using Paris-green, white arsenic, or other arsenites with your Bordeaux Mixture, or any of the former alone, I would keep the calves out of the orchard while spraying is going on and for a few days after. Just at this time of the year, particularly if the calves are pretty well grown, tney feed voraciously, and if one is rather careless about keeping the mixture thoroughly agitated, it may happen that a tree here and there (and the grass underneath) will get an exceptionally heavy dose of the poison. It is only in cases of this sort that injury to the animals may occur. While careful experiments have been made on this very matter, all of which go to show that under ordinary circumstances no danger is to be feared from the application of poisonous substances to trees where animals are pasturing in the same area, yet in one or two instances which have come under my own observation, I have seen sheep seriously injured, so that it will pay to be on the safe side. I would not think that there was the slightest danger of turning the calves into the orchard a week after the spraying was done, or immediately after a shower of rain.

Corn for Green Manuring; Spraying Plum Trees.

What crop is best to sow on a field to plow under? The soil ranges from sandy loam to clay. Sorrel has quite a start, and it is hard to get a cateh of clover started. How would corn do sown this Spring early, to be plowed under when it gets two or three feet high, then follow with wheat this Fall? Would sown corn be liable to sour the land if it was plowed under in hot weather? What is a good spray for plum trees, and how is it made?
So. Livonia, N. Y. H. W. M.

Corn is an excellent soil regenerator for soil which is hard and lumpy. I do not think it is best for light sandy land, but where it is difficult to get a good catch of clover or other of the small-seeded plants then corn is one of the plants that might be used. I do not think there is any special danger of souring the land by plowing under a heavy crop, but there might be some difficulty in getting it well incorporated with the soil and well packed down if the season should prove to be dry. You would find it difficult to cover corn if you allowed it to grow two or three feet high. My view of the best way to treat this field would be to give it a dressing of lime—20 or 25 bushels per acre—and then sow with field peas, plow these under when the pods begin to form, and work the soil thoroughly until time to sow wheat. The spray you should use for plum trees will depend on what you want to kill. As a rule, there are two classes of enemies in the case of the trees, as with other fruit trees, the insect and the plant parasite. The safest and most efficient spray is Bordeaux Mixture with some form of arsenical poison. Plum foliage is more susceptible to injury from sprays than apples, and one should be very careful to have plenty of lime in the Bordeaux Mixture. An excess of lime increases the difficulties of spraying, but it lessens the possibility of injury. Japan plums should be treated with half-strength Bordeaux Mixture.

Lime Paste for Bordeaux Mixture.

R. P. L., Fallsington, Pa.—How many quarts of lime paste (free from surface water) will be required to equal six pounds of unslaked lime? I have slaked a large quantity of lime, intending to keep it in the paste form, for making Bordeaux Mixture, but do not know how much of this paste to use to complete the formula. Is the ferrocyanide test reliable, and will it make a good mixture to add a little lime at a time until this test is satisfied?

ANS.—You can answer this yourself better than anyone else, by trying your lime paste. Use the usual amount of sulphate of copper and add the lime paste until the change in color from the ferrocyanide takes place.

Orange Growing in Porto Rico.

J. D. K., Mt. Airy, Philadelphia, Pa.—Will Mr. Platt (page 337) tell us something more about orange culture? How do Porto Rico oranges compare with Florida fruit? What is the average yield of trees 10 and 12 years old, and have they off years of bearing like apple trees? What is the net income per box to growers, when shipped to New York?

ANS.—There has been no orange culture in Porto Rico up to the present time such as Florida and California growers give to their groves. Of course I am unable to tell about orange culture when there has been none. The Mirangha or sour orange of Porto Rico resembles the wild sour orange of Florida. Neither is edible. The sweet oranges are all seedlings, and differ in quality and value. As a rule, they are inferior to the improved varieties of Florida. Nearly all the orange trees are growing where the seed chanced to fall I have no data for stating the yield of 12-year-old trees. The orange, like the peach, bears every year. The oranges shipped to New York the past season gave little or no profit to the grower. Careless handling and bruising of the fruit before packing caused much loss. At present the fruit of Porto Rico for export does not amount to much. I have great expectations for the future.

CHILDS'
SO-BOS-SO
KILFLY

COWS Will GIVE FROM 15% TO 25% MORE MILK
and Better Milk if Protected from Flies by the use of CHILD'S SO-BOS-SO KILFLY.

It is a thorough fly killer and germicide, it destroys all baeterial germs, insures health, greater strength and vigor to the animals and by the absolute relief afforded to them increases the amount of milk $8.00 to $10.00 per cow during the season you will find it the best investment you ever made.

It allays nervousness in horses as well as cows and keeps both in better general condition. As an antiseptic and for scours in calves, hog cholera, swine plague and foul in cattles' feet it is unequaled and may be used either in the stable, cow shed, chicken house or pig pen.

It is easily and rapidly applied with Childs' Eleetric Sprayer, and a herd of 30 to 50 cows can be sprayed in a few moments. SO-BOS-SO is absolutely harmless to man and beast.

Abortion in cows, which is caused by a germ—propagated by unsanitary conditions—can be prevented by the use of SO-BOS-SO KILFLY.

Sold only in gallon cans. Ask your dealer or send $2.00 for one gallon can and Eleetric Sprayer complete, seeurely packed and express paid to any point east of the Mississippi River exeept State of Maine.

The Sprayer can also be used for spraying potato vines, bushes, trees, etc. Beware of imitations.

CONVENIENT. CHEAP. PRACTICAL.

Thousands are in use in America, Canada and Mexico. Shipments have begun to Cuba, the Philippines, South America and Australia.

LENOX, Mass., April 21st, 1900.
I have used **So-Bos-So Kilfly** with good results. It is a comfort to both man and beast at the milking time. JACOB STEIBEL,
Supt. to the Hon. John E. Parsons.

PHILADELPHIA, PA., May 2, 1900.
Last July the daily quantity of milk produced by my Chester County Dairy fell off very considerably, which I attributed to the annoyance which the cattle received from the flies. About half the time the herd was standing in a stream switching instead of grazing. I ordered a sample of **So-Bos-So Kilfly** and by having it applied every second morning, greatly relieved the herd and increased the milk product from 15 to 25 per cent, and I have continued to use **So-Bos-So Kilfly** during hot weather ever since that time. Our herd of about twenty head could be sprayed in the stable in less time than it would require to milk a single cow, and I consider that I saved many times the cost of the **So-Bos-So Kilfly** used in addition to affording comfort to the herd. G. S. W. BRUBAKER.

LENOX, Mass., April 23, 1900.
We used **So-Bos-So Kilfly** last summer, on cows and horses with excellent results, it being much more satisfactory than anything else of the kind we have ever tried.
A. H. WINGETT, Supt. Allen Winden Farm.

CHAS. H. CHILDS & CO., Sole Mfrs., 12 LaFayette St., UTICA, N. Y.

Ruralisms

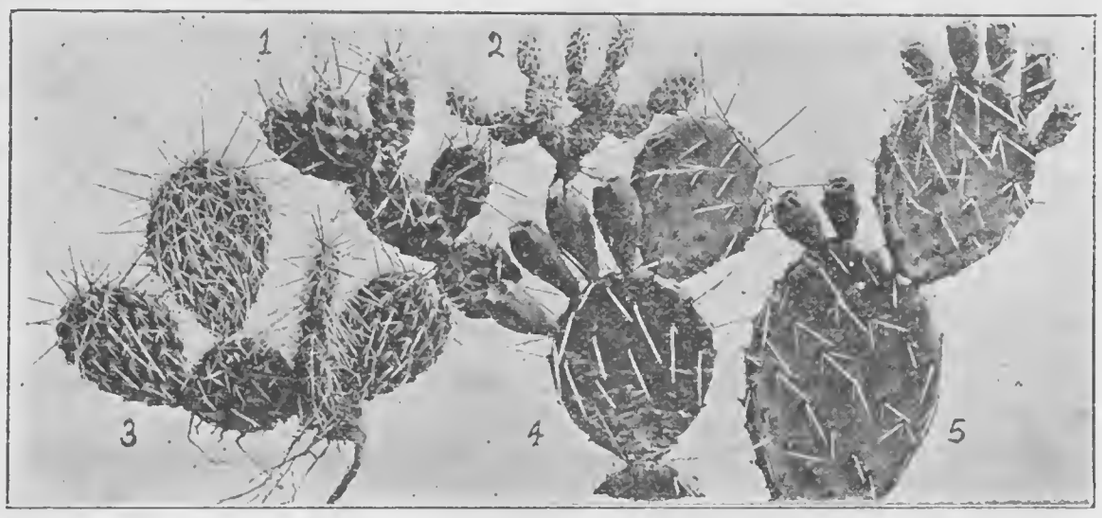
NOTES FROM THE RURAL GROUNDS.

HARDY CACTI FOR DRY SLOPES.—About the only hardy cactus grown in eastern dooryards is the common prickly pear or Indian fig, Opuntia vulgaris. It is a native of the Eastern States, and is reliably hardy when planted in congenial situations as far north as Massachusetts. It will wrinkle and discolor when exposed to severe cold, but soon regains its plumpness on the advent of warm weather. It thrives best on rocky slopes where there is good drainage, as water about the plants is injurious at any time, and generally fatal in Winter. The common prickly pear is a rather flat-growing species with pale yellow flowers about two inches in diameter. The fruit or berry is edible, but there is very little of it to eat. In the South and West O. vuigaris is replaced by two or three closely-allied species, O. Rafinesquii often producing flowers with an orange-red center. None is superior to the common species for ornamental planting. Many odd species of caeti are native to the arid slopes of the Rocky Mountains, and a dozen or more occur at considerable elevations, where the Winter temperature often descends to 20 degrees below zero. D. M. Andrews, of Boulder, Col., who publishes a most interesting catalogue of desirable native plants, sent the Rural Grounds a collection of seven species of hardy mountain cacti in April, 1900. They were planted, according to his advice, on a forbiddingly sterile slope; part of an old sandstone quarry, where the gravelly soil is too poor to grow Potentillas or "five-fingers." There were five species of Opuntia, all of which are represented in the picture, Fig. 159. They soon started into growth and produced many large, brilliant yellow blooms during the Summer, followed by showy crimson and purple fruits. They have endured the past trying Winter with but trifling harm. Two speeies of hedgehog cactus, Cactus viviparus and Echinocactus Simpsoni, accompanied the Opuntias, and were planted at the same time and place. They also endured the Winter without harm and are now, May 15, blooming brightly. C. viviparus has large brilliant purple flowers, and those of E. Simpsoni are shell pink. These cacti are apparently indifferent to dry cold, but often suffer from stem rot if water settles about them in Winter. They do best on a dry slope or rockery, where the drainage is perfect at all times, and may be made very decorative. They satisfy a liking for something grotesque and could be used to good effect oftener than they have been in the past.

The genus Opuntia is quite extensive, over 130 species having been described. They are chiefly distributed in the semi-arid regions of the American continent, and are particularly numerous from Mexico to the south temperate zone. Some of the largest cacti known are Opuntias; they grow into trees 20 feet high, with spreading, clumsy tops. In some countries the fruits of O. Tuna and O. Ficus-Indica form an important article of diet, and are extensively grown. This is especially the case in Sicily. The people of that island almost subsist on them during the Summer months, and in Mexico, the native home of these fruit-bearing species, the culture is almost as prominent. The fruits are very nutritious and quite palatable. Efforts are being made by the National Department of Agriculture to introduce the best varieties in the favorable climate of California and the Southwest. Opuntias are also much used for hedges, and to some extent in very dry regions for forage, but the numerous spines sooner or later irritate the digestive organs of the animals to which they are fed.

A GOOD SPRAY CALENDAR.—The new spray calendar issued by Leggett & Bro., New York, contains more useful information in compact form than we have found in any similar publication. Though primarily devoted to the preparations of the Messrs. Leggett, it gives full formulas and directions for using all effectual insecticides and fungicides, with dates for treating many useful plants. No better work than this has been issued by our experiment stations.

ASPARAGUS THAT'S FIT TO EAT.—Several years ago Ruralisms called attention to the miserable table quality of the higher grades of asparagus sold in the city markets. These fancy bunches are made up of thick and corpulent stalks, cut six or seven inches below the surface of the ground, leaving an edible tip seldom more than two inches long. The bleached and tough subterranean portion is not only useless in itself, but to many tastes unpleasantly affects the flavor of the edible tip. The purchaser really pays an extortionate price for the small useful portion. For certain forms of fancy cookery short tips are indispensable, and some misguided persons even think they prefer the bleached stalks to the tender and succulent green shoots cut, as they should be, at the level of the soil after they have grown seven or eight inches high. The demand for bleached asparagus is still so great that growers almost universally ridge up the soil several inches high above the plants just before the growing season, flatten the ridges to a uniform height by means of a speeial tool, and cut the asparagus by stabbing it through the side of the ridge, just after it has broken through the apex. The bunches, when made up of asparagus harvested in this manner, are very attractive to the eye, but very much of a delusion to the economical housewife. There are signs of a reaction, or at least a growing discrimination on the part of consumers, as quotations of green asparagus are now being made at very good prices. What are known as seconds in the retail markets, made up of small white and green stalks, may often prove more satisfactory to the buyer than the higher priced quality with its minute edible portion. Asparagus is one of the most acceptable of all Spring vegetables, and can still be grown very cheaply in spite of the rust and beetle. The absurd demand for a large percentage of the inedible portion in order to satisfy the eye, can only arise from ignoranee of the true charaeter of the plant, and when buyers refuse to accept what they cannot eat the consumption will enormously increase. The rule on the Rural Grounds is to allow the stalks to grow several inches high, and snap them off at the surface, rejecting all portions which will not break with a clean fracture. Just at present the retail price of asparagus ranges from 15 to 25 cents a bunch, weighing two or three pounds. The highest figure is for bunches eontaining all large bleached stalks showing only a tip of green, and the lowest for mixed bunches of white and green. There is little doubt but that the consumption of green asparagus is increasing. W. V. F.



FIVE HARDY ROCKY MOUNTAIN OPUNTIAS. FIG. 159.

1. Opuntia Arenaria. 2. Opuntia Fragilis. 3. Opuntia Polycantha. 4. Opuntia Mesacantha. 5. Opuntia Phaeacantha Major.

Spring Show of the N. Y. Hort. Society

The Spring show of the New York Horticultural Society was held in the hall of the Museum Building of the New York Botanical Garden, Bronx Park, May 8-9. As a first attempt of the new society it may be considered a gratifying success. The exhibits were chiefly confined to conservatory plants, though some lots of rare evergreens were included. There was a notable collection of cacti, Agaves, and other succulents. On a first view these spiny and tortuous forms of vegetation suggest a morbid taste in the grower, but a close inspection reveals a wealth of beauty in form and quiet color. Some of the metallic shades are very fine. May is not usually a season of bloom for orchids and choice greenhouse plants, but a number of fine specimens were brought together from various sources, and made a bright show. One of the best exhibits of meritorious plants was made by H. A. Siebrecht & Son, New Rochelle, N. Y. The lateness of the season has greatly retarded vegetation in the Park, but many interesting bulbous plants were in bloom.

W. V. F.

ONION SMUT.—During the past few years several of our experiment station workers have been studying out a remedy for onion smut. As most onion growers know, this disease plays havoc with the crop. In many cases it has been so bad that it has nearly ruined the business. Transplanting seems to be a pretty sure remedy for it. Under this system the seed is sown in sterilized ground, so as to avoid the smut, and, when the little onions are of the proper size, they are transplanted into the field. Many growers feel that they cannot go to the expense of transplanting, although in some cases it has been done with success. At the New York Experiment Station at Geneva, experiments have been made with a mixture of lime and sulphur. It has been found that equal parts of air-slaked lime and flowers of sulphur put into the drill with the onion seed proved quite effective. The lime and sulphur sown broadcast over the ground does not seem to give the best results, but, where the mixture is put directly into the drill with the seed, excellent crops have been raised. In order to apply this mixture a new form of drill was necessary, and extra boxes, tubes and agitators for distributing the mixture were placed at the top and side of the drill. The cost was not much greater than for the ordinary seed drill, while the mixture was applied evenly and put where it would do the most good. The Ohio Station has also conducted experiments along this line, and found that lime and sulphur gave excellent results. It was also found that a solution of formaldehyde in water, sprinkled along the row on the seed in the ground, was very effective. Of course this would necessitate sowing the seed by hand, but it is possible that soaking the seed in the formaldehyde before sowing would help.

Mr. A. H. Nickerson, of Howland, Me., writes: "I used Bowker's 'Boxal' on my potatoes and was well pleased with its effect and the benefit derived. It serves two purposes—destroys the bugs and preserves the tops."—*Adv.*

Hope Farm Notes

TIME TO QUIT.—As it is still raining I will try to discuss something more cheerful than potato prospects this week. They tell me that discussion "brings out all there is" in any subject. If there is any more rain locked up in the weather clerk's chest I wouldn't for the world say anything that would "bring it out." We have had all we need and a surplus. Let's have something cheerful—here it is from a Massachusetts reader:

"I note with interest what you have to say regarding the age limit. I think 45 too young. I think a man should 'keep the saddle' till 60 at least. I shall be 47 soon, but do not expect to begin to grow old for 20 years yet. I put in 10 hours a day as an 'industrial slave,' and for recreation care for about an acre of fruits, vegetables and flowers. I feel no older than I did 25 years ago. I still love a long day in the woods, and am still counted as 'a good man' on the base-ball diamond. I do all my cultivating and plowing (except turf) with hand tools. I have never tried to run this piece of human mechanism with alcohol or nicotine. I do not believe hard work will hurt me as long as I eat well and sleep well. I am acquainted with a farmer of 95 who helped haying, cultivated quite a piece of potatoes and corn last Summer, and is planting potatoes this Spring. I have also known men 70 and 75 knocking off good day's work in the shop as cheerful and energetic as though 50 years younger. I am inclined to think that a man is just as old as he feels." C. A. B.

Indian Orchard, Mass.

I have been reading a delightful book by Dr. J. J. Black, of Delaware, called "Forty Years in the Medical Profession." Dr. Black says "a man is as old as his arteries," and he goes on to tell some of the ways in which the arteries are broken down. I am startled to see how much diet and plain, honest living have to do with prolonging life.

LONG LIFE.—The question arises—how long would we live could we regulate life exactly? Few would measure it by years, but rather by health and the ability to enjoy and master the forces of nature. I have lately been talking with two celebrated experts about these things. They are very hopeful for great future victories over the germs which cause and spread disease. If we are to judge from the past, they say, scientists will yet master even the worst diseases, and practically drive them from the earth. Even now some cases of consumption are being treated by cutting through the ribs and either taking out a part of the lung or filling a diseased cavity with a healing liquid or gas. When these good days come the average pill-giver or drug doser will have to saw wood for a living. While we are not there yet we are coming to it. I asked my expert friends this question: "Take a child well born, with healthy parents—and keep him under constant care so that he should not overwork or weaken any organ, or permit the germs of any disease to make serious inroads in his body—how long could you make him live?"

"Most likely for 150 years!" "But," added one of them, soberly, 'the last half of that life would not be happy. In spite of his health and good condition the man would be a 'back number.' The friends of his youth would be dead, and old men do not make new friends readily. Such long life is possible, but the majority would vote it a mistake."

PLAIN LIVING.—That seems sensible to me. I do not think I should care to live with the mere shadow and ashes of life around me. The very old are too often called upon to drink of the bitter dregs of the cup of life. It is evident, though, from what these doctors say, that this husbanding of the powers of mind and body is a matter of plain and right living. As for "eating well," I believe that for the man past 45 that means eating less than before, with more fruit and less meat. "Always leave the table a little hungry" is good advice to the grown-up man! No man can abuse his body with rum and tobacco and play baseball so well at 47 that the boys will choose him for an important match. I am a little fleshy at present, but if our friend will go behind the bat I will pitch for a few innings. That would make a "battery" of over 90 years, but we might make some of these smart young fellows "fan the air" after all. Plain and clean living, a good square effort to do your duty, fair dealings with all men, a curb bit on your temper, faith in the good and thought before action—that strikes me as a method both sensible and scientific of keeping the germs of waste and worry out of the body. As for the time to quit, as we never know when that time will come, why not try to be always ready? Right here I might add a thought that has caused some discussion between the Madame and yours truly. She read somewhere that trouble and trial sweeten and develop character. I asked her to name a character among our friends that has not been embittered and made caustic by trouble—long drawn out and well rubbed in. To my surprise she quickly named several. I thought I could quickly match them with trouble-soured individuals, but I think she beats me!

FARM NOTES.—We have a new reason for seeing some value in this cold, wet weather. Grandmother is in a hospital in New York recovering from a serious operation. Those who have had some friend under the surgeon's knife know what it means to wait for news from the sick room! Hot, basting weather would be bad enough for Grandmother, but this cool wet weather is in her favor. So when the rain slides down we can say: "It's good for the patient, though bad for our patience." Yes, the rain is good for grass, grain and Grandmother at least. . . . . We have begun to feed the green rye and clover to the stock. I would like to cut this grain for hay, but it could not be dried in any such weather. Rye hay is poor stuff if it stands too long. . . . . The Crimson clover came out nobly. During the early Spring it dawdled along, making little if any growth. Suddenly it jumped up, and is now a fine crop Cut with the rye it makes great cow feed. . . . . The grass on the field where that Clark method of seeding was tried has improved. It is very thick, but not quite so tall as that on old meadows. I have no fields for comparison where the grass was sown with grain, but there are complaints that while the Clark grass fields are thick they do not grow fast. One trouble evidently is that such fields were not fertilized as they should have been. You would hardly expect a pasture to provide for five cows as well as it provides for three. One great principle of the Clark method is that by using double the quantity of seed, and thoroughly fitting the soil, we more than double the number of growing grass plants. Of course, these plants must be well fed and watered if we expect them to make a satisfactory growth. I now expect one of my fields, at least, to give a heavy yield of hay—and pay for the extra time and seed. . . . . A part of our potato crop is six inches high. That part is, however, limited to *one plant*. You will remember a picture on page 265 of THE R. N.-Y. of a potato that had grown into a bone. We planted that in a large pot, and then plunged the pot into a box of earth. I wished to study the root growth of that plant. It is very vigorous, and seems to be taking the strength out of that bone, which was part of the thigh of some animal. That plant grows as if the bone came from a "kicker," like Julia, with power to transmit its vigor. Our main potato crop is very late—part of it not yet in the ground. On farms near us the crop seems to be coming up slowly and unevenly.

H. W. C.

The Time to Quit.

Some men must quit at 45 and from that on until the time comes that they must quit if there be a "younger hand to take the reins" or no, and it does not depend altogether, either, on the question of right living. I knew a man who died at the age of 83 who probably would not have lived much past 70 if he had been relieved of all necessity for labor at 64 or 65. F. H.

Plymouth Co., Mass.

Yes, 45 is none too early to begin to get ready to get out of the harness. Suppose, as "Michigan Farmer" says, 15 of the best years of life should then be ahead. As farming goes they'll all be needed in order to be in shape to "get out of the harness gracefully." How many at 60 years, who succeed in paying for their farms by that time, scarcely look around and take a long breath before they discover what they have struggled to pay for is almost turned to ashes in their hands when they try to sell or rent? The price has gone down, the buildings and fences have "aged" as well as he, and at best are not "up to date" in equipment, and he'll be inclined to blame the tenant for lack of care, when in fact things were just ready to go to pieces. A. WETMORE.

ALFALFA SEEDING.—I see the question is asked about seeding on Winter wheat and with Spring grain. I have seen a good catch on the wheat where a smoothing or light harrow is run over the ground. The majority of the farmers here sow on the Spring grain that has a light amount of grain sown not to exceed 1½ bushel to the acre. The Alfalfa is sown in front of the drill. Hundreds of acres are seeded in this manner, while but few seed alone. C. M.

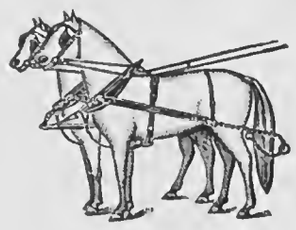
Onondaga Co., N. Y.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

For the land's sake, use Bowker's Fertilizers. They enrich the earth.—*Adv.*

No. 5034, Concord Spring Buggy. Price $60.60.

No. 2016 Canopy Top Carriage. Price $98



No. 602 Team Harness. Price $18.90.

No. 2034 Buggy. Price $38.30, with leather quarter top.

Buy Your Carriages Where They Are Made

You can save two profits by buying your carriages, buggies, phætons, surreys, wagons or harness right from our factory. We are **manufacturers** of vehicles and harness, and are absolutely responsible for every article that leaves our place. You not only have an absolute guarantee of protection, but you make

A Great Saving

It is an actual fact that you can purchase a vehicle or harness from us for 25 to 35 per cent less than you can get the same value elsewhere. **We sell at wholesale prices,** have no agents or salesmen to pay. You get the benefit of all this saving as well as the dealer's profit.

With every purchase is a written guarantee that if the goods we send you are not satisfactory, you can return them. We will pay freight charges both ways. Send for manufacturers' catalogue and see for yourself. It costs you nothing.

THE COLUMBUS CARRIAGE AND HARNESS COMPANY, Box 772, Columbus, Ohio.

THE WHEEL OF TIME for all time is the **Metal Wheel.**

We make them in all sizes and varieties, TO FIT ANY AXLE. Any height, any width of tire desired. Our wheels are either direct or stagger spoke. Can FIT YOUR WAGON perfectly without change.

NO BREAKING DOWN.

No drying out. No resetting tires. Cheap because they endure. Send for catalogue and prices. Free upon request.

Electric Wheel Co. Box 88 Quincy, Ills.

BUGGIES AND HARNESS

HARNESS $4.15

THIS $50 TOP BUGGY $28.50

YOU CAN BUY FROM US AT FACTORY PRICES BUGGIES, PHAETONS, SURREYS, WAGONS, ALL KINDS OF HARNESS. We will sell direct to you a vehicle or harness as cheap as dealers buy their goods in car-load lots. Don't pay profits to middlemen. Our work is all high-grade, correct style, and elegantly finished.

SEND FOR FREE CATALOGUE SHOWING LARGEST LINE VEHICLES AND HARNESS IN THE UNITED STATES.

All Work Guaranteed and Shipped on Approval.

DR. WALTER VAN FLEET, H. E. VAN DEMAN, MRS. E. T. ROYLE, } Associates.
JOHN J. DILLON, Business Manager.

SUBSCRIPTION: ONE DOLLAR A YEAR.

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs.

"A SQUARE DEAL."

We believe that every advertisement in this paper is backed by a responsible person. But to make doubly sure we will make good any loss to paid subscribers sustained by trusting any deliberate swindler advertising in our columns, and any such swindler will be publicly exposed. W protect subscribers against rogues, but we do not guarantee to adjust trifling differences between subscribers and honest, responsible advertisers. Neither will we be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent us within one month of the time of the transaction, and you must have mentioned THE RURAL NEW-YORKER when writing the advertiser.

Name and address of sender, and what the remittance is for, should appear in every letter.
Remittances may be made in money order, express order, personal check or bank draft.
THE RURAL NEW-YORKER,
409 Pearl Street, New York.

SATURDAY, JUNE 1, 1901.

THE subscription offer on page 380 is the best we have ever made. Two subscriptions to THE R. N.-Y. for the remainder of the year, two Ruby Queen roses and a copy of "The New Horticulture." Where can you possibly find a larger dollar's worth? The book, by Mr. Stringfellow, is very interesting and valuable. It is "easy to read," as one reader well puts it!

*

MR. COOK has a thoughtful article on page 398 regarding the tenant system of managing the farm. We agree with him that improvements on our own farm are better than a mortgage on another farm Again and again we see the bad results which follow when farmers move to town and leave the old farm to a careless tenant. Far better stay on the farm and try to bring the town to it by encouraging free rural mail delivery and telephones.

*

SOME men forget their hats or umbrellas. Some forget to sign their name to a letter, or to give post office or State. They are so well-known locally that they forget that people in other localities never heard of them. They sometimes write important letters and find fault because they are not answered. The fault lies with themselves because they left out name, State or post office. The simplest remedy for all this is to have name and address printed on your paper. Put the name of the farm there, too.

*

AFTER a desperate struggle the farmers of Pennsylvania have won a victory in the passage through the State Legislature of a strong anti-oleo bill. It was a hard and long battle, in which the State Grange and other organizations took part. The oleo interests were strong and well organized, and they fought desperately for their fraudulent profits. The farmers did not have much money, but they made a brave showing when they organized for business. Why do we keep on talking about organizing and "getting together?" Because that is the only way to turn the wrongs of the farmer into rights.

*

THE history of last year's apple crop is still fresh in mind. All through the season there were reports of a "heavy crop." Many farmers were deceived and sold their apples for half of what they should have brought. The only way to prevent another blunder of this sort is to have better understanding of the crop conditions, and to know what prices are offered. It is just such information as this that the New York State Fruit Growers' Association wants to collect. In order to make its reports valuable there must be many of them—sent by individual farmers. Thousands of farmers should join the Association at once. It gives them a chance to "get together" for mutual help. Write at once to F. E. Dawley, Fayetteville, N. Y., secretary, or L. T. Yeomans, Walworth, president.

*

YES, a "retired farmer" might do much for his country if he would. We do not refer to the farmer who rents his farm to some careless tenant, and moves to town in order to find fault with society in general. Such a man is not only retired but tired. The ideal retired farmer trains one or more of his boys so that they love the farm. These boys pick out farmers' daughters for wives, and all live happily together. Thus relieved, the old gentleman retires from hard, active work and stays on the farm. His council and experience are useful in public affairs Society has protected him, and given him fair opportunities, and now he pays part of the debt—not as a general critic of the universe, but as a helpful and inspiring example. It is very easy to become sour and bitter during the last years of a busy life, if we narrow the point of view down to our own individual wants and troubles. There ought to come to the declining years of every worthy farmer a fair, calm view of life in which he may realize how much he owes to others.

*

ONE of the most inconsistent things we have seen is the habit of a man in a small village, who harnesses his horse and drives to a large town four miles away, urging the animal to such an extent that he is covered with foam when he arrives The man does not do this because there is any need of hurry, for he sits around in the stores and gossips the rest of the day. A stranger seeing him go would think he was after a doctor, the fire department or a political appointment, but the neighbors only laugh at his ridiculous actions. Such a "bluff" does not amount to much anyway, and does not deceive. The saddest thing about a bluffer is the fact that he seems to believe in his own bluffs.

*

NOT long ago a celebrated minister went to a country neighborhood to preach. A large audience greeted him, and he gave an eloquent discourse on "Unselfishness." As he walked out a man stepped forward to thank him for the sermon. "It was good," he said, "I hope it will help make our people unselfish!" "Yes," said the minister, with a half sigh, "I hope so, but you must remember that the people are called upon to give for many different things!" "You are mistaken," said the man, "I did not say *generous*—I said unselfish!" There is material for a year's thinking right in that sentence. Many people cannot see the real distinction between the two words. The great work for the world's uplifting requires personal sacrifice. The "generous" people like to hire substitutes to do the real fighting for them.

*

WE have received a complete report of the hearings on oleomargarine before the Congressional committees last season. It makes a book of over 900 large pages, weighing three pounds. This big document contains what was said for or against oleo by the friends and foes of the Grout bill. We believe that any fair-minded man who will study this report will see that the arguments of the oleo people are founded on bluff and deception. One of their most "eloquent" champions undertook to defend what he called "innocent deception." What a beautiful, kindly thing it is to color lard and suet and then sell it as butter! These men always dodge the living issue, which is the fact that they use the yellow color in order to deceive. They attempt to steal the livery of the honest cow for the benefit of the hog and steer!

*

PACIFIC coast dairymen are naturally much interested in the adjustment of the Philippine tariff as regards butter and oleo. The Taft tariff proposes a differential of half a cent a pound in favor of butter; the dairymen consider this not nearly enough, and believe that oleo should be subject to a duty of at least 10 cents a pound. The oleo ships to the tropics much better than genuine butter, the beef tallow it contains keeping it firm, and it does not lose its flavor during a sea voyage. It can be made to stand any climate much better than the delicate butter fats. If it is admitted to the Philippines at almost the same rate as butter, dairymen will be able to do little business with the Islands. If butter has a fair chance against oleo, the Philippine trade will provide a great stimulus to dairy industries on the Pacific coast.

*

THE State of California seems to have "taken the lead over every State and country in the world" in fighting insects. There are State and county boards of horticultural commissioners, a State Board of Horticulture and a quarantine officer. All these various boards are not mere boarders, for they do actual work. Nursery trees are inspected before they can be brought into the State. The State law reads as follows:

Whenever a petition is presented to the board of supervisors of any county, and signed by 25 or more persons who are resident freeholders and possessors of an orchard, or both, stating that certain or all orchards or nurseries, or trees of any variety, are infested with scale insects of any kind, injurious to fruit, fruit trees and vines, Codling moth, or other insects that are destructive to trees, and praying that a commission be appointed by them, whose duty it shall be to supervise their destruction, as herein provided, the board of supervisors shall, within 20 days thereafter, select three commissioners for the county, to be known as a county board of horticultural commissioners.

Local inspectors are employed. Each inspector examines all the trees in his district. If any of the (comparatively) harmless kinds of scale are found, the owner is notified, and nothing more is done by the inspectors, as they yield to a wash of whale-oil soap, or disappear after a season of hot weather. When White scale are found the inspector starts a colony of ladybirds imported from Australia (Vedalia cardinalis). For this there is no expense to the owner of the orchard. The cost to the owner whose trees are afflicted with the kinds of scale that require gas treatment is say 50 cents per tree, which the owner gladly pays rather than see his orchard destroyed by insects. These methods work well in a State like California, where a large share of the land is devoted exclusively to fruit growing. It is necessary too that the fruit growers should be intelligent and able to "get together." Any such law in a State or community where fruit growers were distrustful and ready to cut each other out would be worse than a dead letter. The only thing that gives force to any public law is the law of private brotherhood or fair combination of personal interests.

*

DURING the last fiscal year this country exported domestic merchandise to the value of $1,307,760,571. The imports during the same time came to $849,941,184—thus leaving apparently a balance of $457,819,387. As this has been going on for some years the people have been led to believe that we have a large balance in Europe and that this is at last a creditor nation. New York bankers say that there is practically no balance to our credit abroad. One of them is reported as follows in the New York Sun:

In figuring the balance in favor of this country on the basis of the net exports of merchandise over the net imports of merchandise, there has been no taking into account of the very large amount of money that rich Americans residing abroad spend there, the money, of course, being drawn from this country. In this category are such men as William Waldorf Astor and Bradley Martin, and such women as the Countess de Castellane and the Duchess of Marlborough. There is a great number of such rich foreign Americans living in London, Paris and Italy, and to them can be added a great many more Americans of less wealth who also live abroad and who spend a very large sum in the aggregate. For example, there are living in the city of Dresden alone 30,000 Americans. Besides all this there is the amount, which has been calculated at $100,000,000 yearly, which is spent by American travelers in Europe. In addition there is the amount of the freights and insurance on our shipments abroad which we pay to Europe. The net balance is very much smaller than the amount which the statisticians have been figuring at.

We have long believed that the ngures given by the statistician needed a good deal of shading. Europe could not buy such vast amounts of American food and machinery if payments were made in cash. So we do not get rid of our grandees when they become too good for their native land and move over the water! They continue to live on American money and absorb our foreign trade balance.

*

BREVITIES.

We like a dose of theory
As well as other folks, but we
Would take a homeopathic dose
And fill the measure, packed down close
With practice clear and hard and plain,
And thus unite the hand and brain.
For every wise man understands
That brains are useless without hands,
For wisdom often idly lingers
Unless worked out through skillful fingers,
And we should mark each quality
This practice is—that theory.
Put labels on so all may know
One from the other as they go.
For we add wormwood to life's cup
Whene'er we mix these labels up.

NOT many Baldwin apples in sight.

THE hen man's credit is a yard wide.

HE only earns a rest—who does his best.

ALL men have judgment but few give it proper exercise.

WE have no authentic report of any injury to live stock from spraying.

MEASURE your prosperity by your debts rather than by your assets.

ARE there any people who really enjoy being swindled? It would seem so!

WHEN rainy days lay you upon the shelf, don't scold your wife but go and scold yourself.

THE letter on "Farming in Mexico" is worth reading even though you never expect to try it.

WHILE farmers in New York are seeding oats farmers in the Gulf States are harvesting the crop.

WE avoid tacks by using tact, though sometimes the tacks grow into spikes for lack of a pounding.

IN our experience too much wheat bran makes pale eggs and pale butter, but strong bones for young stock.

SOME men live by their wind and others by their wits—each one of them will be sized up and find a place that fits.

THE fellows who make a business of criticising everything and everybody usually do nothing else, hence their judgment is N. G.

WHAT shall it profit a farmer and his wife to toil and slave and lay up money by inches only to have their children "blow it out" by yards?

SINCE the mosquito has been shown up as a carrier of yellow fever and malaria the scientists have gone after him with all their tools. They will make holes in his ranks.

ON page 387, Prof. Goff refers to the distal end of potatoes. This means the point farthest from origin or place of attachment—a term often used in anatomy, but not in farm practice.

Events of the Week.

DOMESTIC.—Owing to Mrs. McKinley's critical illness the President decided May 15 to abandon his northwestern tour, and to return to Washington as soon as the invalid's condition would permit. May 23 Mrs. McKinley was greatly improved. . . . . A mine explosion at Farmington, W. Va., killed six men and fatally injured five others May 15. . . . . The car strike at Albany, N. Y. was attended by bloodshed May 16. A squad of soldiers on a car which was stoned fired into the crowd, and two business men standing in the doorway of their store were shot, one dying soon after. Several other persons were injured. May 20 irritation began to lessen, and there was no further violence. The trouble seems likely to be settled peaceably. . . . . Mrs. Lyman J. Gage, wife of the Secretary of the Treasury, died in Washington May 17. . . . . Fifteen cases of smallpox were discovered in a Polish convent at Detroit, Mich., May 17, and the entire institution has been quarantined. . . . . A pronounced earthquake shock passed through Ohio May 17. . . . . Three men were swept to death by a rush of water in a mine at Hazleton, Pa., May 20. The water, which came from a previously unknown pool, was set free by a blast. . . . . Edwin F. Uhl, formerly Assistant Secretary of State, and Ambassador to Germany under the Cleveland administration, died at Grand Rapids, Mich., May 17, from a complication of diseases. . . . . An extensive strike of machinists all over the country was inaugurated May 20, the object of dispute being a nine-hour day at existing wages. About 50,000 men are out, but there is no disorder, and employers are disposed to meet the demand. . . . . Several West Point cadets have been dismissed the service, and others suspended, as the result of insubordination and mutiny caused by the hazing dispute. . . . . May 19, Everet Conway, a railway switchman of Evansville, Ind., brooding over an imaginary wrong done his father in a trade, killed W. C. Garrison and wife, fatally wounded Officer Wallis, wounded two other men, attempted to kill his own father, slew a herd of cows belonging to Garrison and set fire to his barn, and then, surrounded in his own house, commited suicide. . . . . A flood from the Dee and Watauga Rivers swept through the low-lying section of Elizabethtown, Tenn., during the night of May 22, drowned three persons, carried away 62 dwellings and caused damage to the rich farming district of Carter County estimated at $1,000,000. Nearly every farmhouse for some distance along both rivers was destroyed or washed from its foundations, and it is possible the loss of life will be increased when full reports are received.

ADMINISTRATION.—The War Department has decided that in future all regular troops sent to the Philippines shall remain there three years, instead of 18 months. This action is due to the heavy expense of transporting regiments across the Pacific and in sending our relief troops. Medical men in the Philippines have maintained that the enervating climate so reduces a soldier that after two years duty he is not fit for barrack life and the navy has found that long continuous service in Asiatic waters is not conducive to health. Secretary Root believes, however, that after troops become acclimated it is better they should remain in the islands than to bring them home. . . . . Struggle in next Congress over reciprocity with Cuba is predicted at Washington. Administration will exert its influence to secure fair concessions for the Islands. Sugar growers and possibly other interests will strongly oppose any reductions of duties. . . . . Purchase of Danish West Indies is not completed, but negotiations are under way. United States is expected to acquire the possessions for $4,000,000 as a precautionary measure in defense of the Monroe doctrine.

PHILIPPINES.—In connection with the commissary frauds at Manila, the following sentences will be promulgated: Captain Frederick J. Barrows, Thirtieth Volunteer Infantry, late depot quartermaster of the department of Southern Luzon, who was charged with embezzlement and selling Government property, to be dishonorably discharged and to undergo five years' imprisonment. Lieutenant Frederick Boyer, Thirty-ninth Infantry, formerly depot commissary at Calamba, on Bay Lake, on similar charges, to be dishonorably discharged and to undergo one year's imprisonment. Both Barrows and Boyer will eventually be removed to Leavenworth Prison, Kansas.

GENERAL FOREIGN NEWS.—Andrew Carnegie has given $10,000,000 to four Scotch universities—Edinburgh, Glasgow, Aberdeen and St. Andrew's. The fund will provide for Scotch students only. . . . . It is announced officially that the British Government is unalterably opposed to raising the import duties in China to 10 per cent, as security for the payment of the indemnity, and that Great Britain would only consent to such a raise of duties in connection with commercial improvements in the Chinese fiscal system.

FARM AND GARDEN.—Statistics just published by the International Sugar Association show that Germany's beet sugar acreage this year is 1,165,170 acres, or an increase of 69,947.

One of the largest tobacco deals ever made in the West has just been carried through at Madison, Wisconsin, by the sale to a Philadelphia firm of 13,000 cases of last year's crop of Wisconsin tobacco. About $350,000 cash changed hands. The shipment will amount to about 260 carloads.

This year there has been planted 1,200 acres of cantaloupes in Pecos Valley, N. M., with an estimated yield of something less than one carload to the acre. Chicago will be the market, and the minimum price per carload is fixed at $300.

California horticulturists are preparing to test the pistachio nut in the San José Valley. The nut of the pistachio tree contains a greenish kernel of an almond-like taste, which is extensively used by the Turks and Greeks as a dessert nut and in confections, and is also exported. It yields a wholesome food oil.

The Ontario County Fruit Growers' Association was organized at Canandaigua, New York, May 4, and will coöperate with the State association organized at Syracuse in February. The following officers were elected: President, S. D. Willard, Geneva; first vice-president, Thomas B. Wilson, Halls Corners; second vice-president, W. S. Marks, Hopewell; secretary, Harry G. Chapin, East Bloomfield; treasurer, Clarence T. Ottey, Seneca; executive committee, Thomas B. Wilson, chairman, W. I. Cumine, Bristol; C. P. Whitney, Phelps; E. L. Moody, Gorham; H. G. Chapin, East Bloomfield.

Seedsmen report an increased demand in New York State for dwarf Essex rape, cow peas, Soy beans, Awnless brome grass and Alfalfa seed. It is evident that the farmers are making practical application of the newest ideas in agriculture.

The Mt. Gretna Agricultural Exposition will be held at Mt. Gretna, Pa., August 19-23.

Commissioner of Internal Revenue Yerkes has decided that where a retail dealer in oleomargarine carries on business at two or more stalls in a market building at the same time he is required to take out and post up a separate special tax stamp at each stall. But where he conducts this business at separate stalls on different days of the week, one special tax stamp, taken out for the market building, is sufficient when posted up at the stall where he is retailing oleomargarine.

Prof. S. M. Emery has resigned his position as director of the Montana Experiment Station, which he has held for the last seven years, having accepted the position of manager for the Manhattan Malting Co., Manhattan, Mont. This concern operates the largest barley farm in the country.

Prof. L. C. Corbett, lately horticulturist at the West Virginia State Experiment Station, has entered the service of the U. S. Department of Agriculture and takes charge of the new 400-acre experimental ground to be known as Arlington Farm.

The Snyder-Harris Oleo Restriction bill, which had passed the Pennsylvania House, was passed finally in the Senate May 22 by a vote of 41 against only 1, Senator Magee, and now goes to the Governor. Senator Muehlbronner explained to the Senate that he would not vote, because he was interested in the business affected by the bill. Senator Snyder says of the bill: "Of the several clauses which affect the interests of the farmers of the State the first is the color clause, which forbids oleo from being colored in imitation of yellow butter and fixing fines and penalties for violation thereof. The second feature of the bill prevents dealers from selling oleo for butter until their cases have been decided by the courts. This feature of the bill is very similar to the New York law, which has been so effectual in suppressing the sale of oleomargarine. The third feature of the bill lets one-half of the fines go to the informer, as under the law of 1885 providing for the suppression of illegal traffic in oleomargarine. The bill provides also for a license which each dealer of oleo must obtain from the Agricultural Department before being permitted to sell the substance. The penalties for violation of the act are similar to those in other States that have succeeded to a great extent in suppressing this fraud."

The California Raisin Growers' Association outlook is quite promising. New three-year contracts are being signed, and extra work done to get outside growers to join. Things are not going quite so smoothly in the Prune Association, and there has been serious opposition to the re-election of President Bond and the old board of directors. Indications now are that the old officers will be continued. These organizations are so large that they are difficult to handle, and it is no wonder that numerous mistakes have been made. It is doubtful whether any board of directors will ever be able to handle such an elephant so that no one will get his toes trodden on.

CROP PROSPECTS.

All kinds of fruit trees are in full bloom. No frost to harm anything yet. Apple tent-worms are not as plenty as last year. C. M.

Syracuse, N. Y.

Never were prospects better for a large fruit yield than at present; plums and pears in full bloom and everything betokens a bountiful supply of these delicacies.

Cincinnatus, N. Y. F. M. D.

The latest reports from the Georgia peach section indicate that there will not be quite so many peaches as last season, but that the quality will average better. The works at the largest fruit package concerns are being run day and night to supply the demand for crates.

Plums, pears and cherries are in full bloom (May 23); also strawberries and promise more than an average crop. Apples are also coming out, and are blowing pretty full with the exception of individual trees that overbore last year. The prospect at present is for a fair crop of Winter fruit if we do not get too much frost.

Fly Creek, N. Y. C. M. C.

The crop prospect is fairly good for wheat so far, and young seeding is unusually fine. If we only have enough rain to maintain it the grass crop will be good. Fruit of all kinds but apples promise well for this season. Baldwin blossoms are not very plentiful and, in fact, the trees that bore a good crop last year are not promising well this year. T. B. W.

Ontario Co., N. Y.

Wheat and grass are looking better at present than any Spring for the past three years. Spring grain is all sown, and prospect is good. Corn is not yet planted; season has been unfavorable for getting crops in early, but vegetation of all kinds is making rapid growth; berries and currants are very promising. Peas, cherries and plums are blossomed very full. Apples about one-half; very few Baldwin blossoms; other varieties quite full.

Stanley, N. Y. F. E. V. E.

All our crops and fruit are in good condition. Not so much wheat grown as formerly on account of the fly and low price. Peaches wintered well, and the outlook is good for a big crop. Strawberries are hurt a little on low ground by late frost. We hear no complaint from the farmers about hard times; they complain that farm help is very scarce. Uncle Sam, telephone companies and electric roads are using all the surplus labor of the country. No idle men now, except from choice. The same is true of female help. Good hired help for the aged farmer's wife hard to get. S. S. BAILEY.

Kent Co., Mich.

The prospects for most varieties of fruit—with the exception of apples—were never better in this section. Cherries, I think, have the handsomest bloom I ever saw. Plums and apricots are a close second. Pears—especially Kieffer—are looking remarkably well considering the very heavy crop of last year. Quinces always do well, and we expect that the present year will not injure their good reputation. As far as I have observed apples must take their place at the bottom of the list, although some varieties are blooming finely, including all early varieties, also R. I. Greening. Peaches are an unknown quantity in this vicinity. Owing to frequent rains and cool weather wheat and grass are booming. I have 30 acres of wheat that will reach an average of two feet high, while some by actual measurement measure three feet from crown to end of leaf. The season is backward for corn, beans and potatoes. W. H. D.

Lima, N. Y.

The weather has been very unusually cold and wet this Spring, and must greatly affect crops. Grass is as good as I ever saw it. If 100 represents the average appearance of grass at this season, I should mark the present outlook for grass 125. All trees are very late in leaf and flower; very nearly two weeks behind the normal. Apples are just coming into bloom, but the show is not full. I think not more than one-third of the trees have any bloom. Other fruits are blossoming full, especially plums, though two weeks late. Much land has been too wet to plow up to the present, so, of course, planting is much delayed. The lot I designed for strawberries was so wet that I did not plow at all, but worked thoroughly with harrow, and set the plants. It was a case of using imperfectly prepared land or very late setting, and I chose the former. The season has been ideal for transplanting, and I shall expect the plants to live. My potato field is only partly planted yet, though I have tried to work the land whenever it was dry enough to work. Now another heavy rain is falling which will make it mud again. Peach, plum and cherry trees are in full bloom, and I am wondering whether this cold rain will not prevent good fertilization of fruit. I think I have noticed such results in past seasons. M. M.

Medway, Mass.

GOVERNMENT CROP AND WEATHER NOTES.

There has been slight damage from frost in the Northern Atlantic States, Lake Region and Upper Ohio Valley, Western and Southern Texas, Southern Louisiana and parts of Alabama and Florida are still suffering from drought. On the Pacific Coast the weather has been cool, with an excess of rain in Washington. Corn planting is going on rapidly in the Central valleys, Minnesota and the Dakotas. Large quantities, however, yet remain to be planted in the Northern Atlantic States, where rain has hindered all farm work. Winter wheat is suffering for rain in the Missouri Valley. The grain outlook on the Pacific Coast is promising. The Southern oat crop is in bad shape owing to the lack of rain. Cotton conditions in the Carolinas and Georgia are favorable, but much of the replanted is not yet up in the Southwest. There have been severe hailstorms in North Carolina, which have made havoc on the truck farms. Bloom on late apples in Ohio, Wisconsin and New York light. Indications are that hay crop in New York will be large. The Jersey cranberry outlook is unfavorable, many of the bogs having been damaged by drought last year. Fly and chinch bug reported to be at work in Indiana and Illinois.

Great damage has been done to crops and buildings by floods in Tennessee and North Carolina. The crops of some farmers along the river valleys have been entirely destroyed. The hailstorm in North Carolina seems to have been the worst ever known in that State. Berries, cucumbers, melons, cabbage and potatoes in some of the best garden sections in the eastern part of the State have been ruined. It is possible that the injury to potatoes may not prove so serious as is thought at present, as they stand hard usage better than other vegetables. Charleston vegetables are being cut by drought. Early cabbage is not heading properly, and beans are also suffering. The Charleston beans received at New York for the last week have been inferior. A good many strawberries have been shipped from North Carolina, but the quality has not been up to the standard and they have been sold for correspondingly low prices. Hot weather along the lower coast is ripening the berries very rapidly. Conditions in the peach section of North Carolina indicate fair crop. Delaware and Virginia are shipping plenty of asparagus. Cutting in the Carolinas has ceased. Tomatoes are being shipped from central and northern Florida, but the quality is far from good, a large share of them being tough and tasteless.

CUTTING SEED POTATOES.—We have had a good deal of experience in cutting Early Ohio potatoes, confining most of our efforts to that variety. I have planted this variety of potato under a large number of different kinds of conditions, and last year made a very careful study of the value of the seed and stem end in direct comparison with each other, on a very even quality of soil, using potatoes which were of equal weight, treated for scab, and given an equal weight of piece of each kind. I found no advantage of one piece over the other. From a consideration of work which I have done for the last five or six years along this line, I would say that I have no evidence that there is any variation in favor of either the stem end or seed end, which would affect an ordinary field crop so that it could be noticed. Indeed, I have been unable to draw any conclusions when the work was carried on in the most careful manner. The weight of the piece and strain of the potato seems entirely to govern this matter of the number of stalks and the number of potatoes produced. Very often the same variety of potato, after it has run a number of years from the original, will produce wide variations or strains. I find there is a marked difference in the number of tubers which a given weight of tuber will produce in a hill in the different cases. With a given strain the number of stalks produced from an ounce of seed planted is quite uniform, also the number of tubers produced, provided the conditions are always kept as nearly as possible the same. HENRY L. BOLLEY.

Woman and Home

From Day to Day.

GOIN' BACK.

I've packed my traps and I'm goin' baek
where the fields are green and broad,
And the colts, with their legs all doubled
up, are rollin' on the sod;
They'll smile, I s'pose, when they see me
come, and they'll, some of 'em, likely
say
They thought I'd forsaken the farm for
good the day that I went away—
But let 'em smile—I'm goin' baek—I'm
sick of the noise and fuss,
Where a couple of dollars count for more
than the life of a common cuss;
They'll nobody notice I've went away—if
you told 'em they wouldn't care,
But somebody's face'll be full of joy when
she greets her boy back there.

I'm goin' back, for I've had my fill—I've
saw what there is to see;
The city may still be the place for you,
but it's lost its charm for me;
And won't I be lonesome there, you say,
with the people so far part?
Well, mebby they're few and far between,
but each of 'em got a heart;
There ain't no hundreds of thousands there
to push you around, I know,
Not earin' a cent where you're comin' from
or where you're tryin' to go—
For the one that's jostled day after day
with never a friend to greet,
There ain't a lonesomer place on earth than
the city's crowded street.

I'm goin' back, and you'll stay here and
rush, in the same old way,
Goin' to work and then goin' home—the
same thing day by day—
And you'll think you're havin' a high old
time and I'll pity you, lookin' baek
(From where I whistle across the fields) at
you in the same old traek!—
I'm goin' back, but the crowds won't know,
and they'll still keep rushin' on;
They'll never notice that some one's face
is missin' when I'm gone—
No, they'll never notice that some one's
gone—if they did they wouldn't care—
But every tree'll be noddin' to me when I
turn up the lane back there.
—S. E. Kiser in Chicago Times-Herald.

*

THE fortunate possessor of cut glass must remember that a sudden jar is likely to break such large pieces as salad or lemonade bowls, and it is a direct invitation to calamity to set other dishes inside them. If the glass shelf is crowded, put down small pieces first, inverting them, and then invert the large pieces over them. Take care, however, that a large piece thus resting upon its own margin presses equally all around; if it is uneven the pressure is likely to cause breaking. The glass shelf should be covered with doubled soft linen, under its cloth or doily; this little padding prevents jarring, which is always the greatest source of danger to cut glass, which has been known to break from the vibration of heavy traffic near the house. Pressed glass is not nearly so fragile, but it is always wise to avoid uneven pressure when piling it.

*

WE heard recently of a helpful husband who tried to lighten his wife's work, with results almost as painful as the case of that amateur cook who, in a moment of abstraction, tried to raise a batch of biscuits with tooth powder. He arose very early, and being fond of doing little jobs around the house, he decided that the front porch was dirty and that it would be a fine thing to clean it. Chuckling to himself to think how surprised his wife would be when she came down, he went to the kitchen, got a scrubbing brush and a package of what he thought was soap powder and a bucket of water, and started in to work with an apron tied around him. It was very early, the neighbors were not yet stirring, and he thought it was a great lark. Gaily he sprinkled the soap about, and then, moistening the brush, he got down to work. But the more he scrubbed the more pasty was the result, and after a while bubbles began to show themselves in a mess of what looked like yeast. Just then his wife appeared at the door. "Why, Jack!" she exclaimed. "What in the world are you doing?" "Scrubbing the porch," replied Jack. Mrs. Jack picked up the package which the zealous husband had supposed contained soap powder. "Good gracious!" she cried. "You're using buckwheat flour!" And he was.

PORTER'S linen is one of the new materials shown for shirt waists; it is supposed to resemble the blue homespun worn by French railway porters. It is woven with an uneven thread, to imitate the inequalities of the hand loom, and comes in two colors, a deep rich blue and a lighter color, called washed blue. Waists fastened at the back are the newest among Summer wear; the front is all tucked or accordion-pleated, and overlaid with lace or embroidery. Most of them are buttoned all the way down the back, but some have an opening at the back just down between the shoulders, extending no farther, the garment being slipped over the head like a sweater. Among the handsome Summer

3809 Tucked Shirt Waist,
32 to 40 in. bust.

waists crêpe de Chine takes the place of silk, some very beautiful models buttoned at the back being accordion pleated, overlaid with heavy silk embroidery; they were accompanied by embroidered sashes of the same material, having long ends and a short bow. Simple waists of

3810 Fancy Waist,
32 to 40 in. bust.

crêpe de Chine in delicate colors cost from $5 up; at $7.50 they are tucked, strapped, and quite elaborately made.

*

WE saw a girl steal a spoon in a popular business restaurant recently. Of course she did not call it stealing—she was merely collecting souvenirs. This practice, which seems to us not only dishonest, but also idiotic, is very prevalent. Hotels, restaurants, steamboats and dining cars all suffer from it. The collectors, who really merit the same epithet as the pickpocket who collects other people's purses, pride themselves on possessing "souvenirs" from as many well-known places as possible. Spoons, forks, salt shakers, pepper castors and butter plates are favorite articles of loot, and these petty thefts swell to serious annual losses. Many of the large hotels have handsome monograms or armorial designs on china, glass,or silver, making the articles very decorative, and the "collectors" make every effort to secure them. The fact that such collecting is stealing, and nothing else, does not appear to impress those guilty of it. This lack of regard for the property rights of others often springs from carelessness and indifference rather than actual dishonesty. It is very necessary to inculcate respect for the distinction between mine and thine from earliest childhood. Where parents fail to respect the little belongings of their children they are preparing those children to show a like disregard for the belongings of others.

The Rural Patterns.

The tucked waist shown is of white linen lawn and is unlined, but all cotton and linen waisting materials are appropriate made in a similar manner, while wool and silk are eminently satisfactory made over the fitted lining. As illustrated, the waist is worn with a collar of the material, stock tie and belt of liberty satin. The fronts are laid in narrow tucks from the center box pleat to the arms'-eyes, the first three being continued to the waist line while the remainder are left free at pointed yoke depth to form soft folds below. The sleeves are in bishop style tucked from the shoulders to within a few inches of the wrist where they are left free to form becoming puffs. The wrists are finished with straight pointed cuffs that lap over at the seam. At the neck is a deep straight collar finished with turnover, or protection portions. To cut this waist for a woman of medium size four yards of material 21 inches wide, 3¾ yards 27 inches wide, 3½ yards 32 inches wide or 2⅛ yards 44 inches wide will be required. The pattern No. 3809 is cut in sizes for 32, 34, 36, 38 and 40-inch bust measure; price 10 cents.

Waists closing at the back are very popular, and the example shown is of tucked and plain batiste, with point de Venise lace and is lined with the plain material cut exactly like the outside, except the sleeves, which are made over the plain foundation without lining; but the fitted lining either of silk alone or silk veiled with the material, can be used when preferred. In the case of the model all-over tucking is applied to the upper line of perforations to form the yoke, while the plain material falls to the lower edge. The lace is cut separately and applied over the plain batiste between the perforated lines, the upper edge being sewed to the lower edge of the tucked yoke; but any width of lace or insertion can be used if the upper edge is applied over the yoke edge. The sleeves are peculiarly novel, the contrast between the heavy lace and the delicate material making a most satisfactory effect. The neck is finished with a stock of lace and a chou of liberty silk is attached to the left side of the corsage. When a still more transparent effect is desired the lower edge of the lace can be sewed fast to the plain material and the latter cut away beneath it and the lace in the sleeves treated in similar manner. To cut this waist for a woman of medium size 3½ yards of material 21 inches wide or 2½ yards 32 inches wide will be required when one material only is used; two yards of all-over lace, and ¾ yard of tucking 18 inches wide and 1¼ yard of plain material 32 inches wide to make as illustrated. The pattern No. 3810 is cut in the usual sizes; price 10 cents from this office.

Household Expenses.

SOME INTERESTING FACTS AND FIGURES.

Several months ago reference was made to a Chicago experimenter who had figured down the family living to 15 cents a day. That this is not a specially meager allowance is shown by the following experience from Connecticut:

During a term of 12 weeks I had provisions amounting to $16.82. A child of eight years took one meal daily with me. We had chicken, oysters, spare ribs, etc.; two meals of meat and vegetables each day, and canned or fresh fruit, bread and cake for tea. Counting 336 meals, 252 for myself and 84 for the child, our board bill was just five cents each meal. I am a teacher, and do not keep either cows or poultry. I buy my milk, butter, eggs and chickens; buy my wood and hire it sawed. The only things I had that I did not pay for were some time during the year I had four bushels of potatoes, a barrel of apples and some squashes and cabbage sent me. My rent costs me 50 cents per week; my wood, with chopping, $6.82; oil, $5.70. I use an oil stove for getting dinner and for all uses in hot weather. The whole expense for a year was $84.27; deduct rent, $19; wood, $6.82; kerosene, $5.70, will leave $52.75 for board for 38 weeks, and the child had one meal each day; thus each meal cost five cents. This is the account for the school year of 1899 and 1900. Of course, I cannot tell what I had to eat last Winter; I always have oysters Sunday and Monday mornings.

I can tell what I have had for three days just past. Thursday, after school, I boiled corned beef, squash, cabbage and turnips; Friday noon had some of the same steamed; Friday morning had ham, potatoes and doughnuts; for tea had buns, canned peaches, mince pie and sponge roll. This morning had sausage, potatoes and cookies. Tea or coffee every meal. This noon had baked beans and baked potatoes, and to-morrow shall have stuffed baked pork. I cook dried beef, fish, etc., as my neighbors do; have oranges all the season, strawberries nearly every meal in the season. I think it more fair to reckon by the year, as I buy flour, sugar, etc., by quantities, so cannot tell any one week what my board has cost. I would have to pay $4.50 for board. I live so far from church and from Hartford that I bought me a little horse, and he and I have kept within the price of board ($4.50). I weigh 166 pounds and he kept so fat that I could hardly get my hand between him and the shafts when I harnessed. A SUBSCRIBER.

Some Massachusetts Figures.

I send you an account of our expenses for the year 1900. Although we usually have a nice garden, last year was so very dry that we were obliged to buy what we ought to have raised. What we did raise is down in its proper place. You will probably wonder at some things, but this is a true and accurate account of our year's expenses. I have receipted bills to show for all. We use very little pastry. Old-fashioned New England dishes, beans, brown bread, boiled dishes and such are staples. Our clothes are made by ourselves; my two girls trim their own hats and mine; and with New England thrift we turn and make over garments, and withal manage to look as well as people who buy new continually. I buy the cloth for my husband's clothes and cut and make them, coats, trousers, vests and underwear. We are seldom ill enough to employ a doctor. Some simple home remedy is generally all we need. We own our house and six acres of land, now mostly in grass, my husband feeling too old and lame to do much farming. I have not said anything about insurance or taxes. I have compared this account with similar ones in past years, and they all vary only a few cents. My family consists of my husband, myself and two grown-up daughters. My son is teaching, but at home part of the vacations. Company for a part of the time. The following is an itemized statement of expenditures:

	Groceries.	Meat.	Fish.	Fruit & Vegetables.	Milk.
Jan....	$6.41	$8.75	$1.04	$1.60	$1.60
Feb....	4.25	8.51	.83	1.10	1.20
March	6.75	8.40	1.00	1.50	1.70
April	3.86	5.34	.75	1.80	1.50
May	7.41	9.18	.85	1.60	1.55
June	6.59	9.16	.80	1.75	1.60
July	13.80	9.74	.90	3.05	1.60
August	9.60	13.69	.60	2.20	1.85
Sept....	4.69	8.59	1.30	3.95	1.50
Oct..	6.15	6.21	1.25	2.61	1.20
Nov.....	4.62	8.00	.93	5.25	1.60
Dec..	10.78	10.77	1.00	2.20	1.65
Total	$84.91	$106.37	$11.25	$29.61	$18.55

Four in family 12 months, five in family five months; food, $249.69; firewood, $22.50; coal, $18; medical, $7; clothing, $37; total, $334.19. This amounts to about $6.30 for each person per month. MRS. A. C.

Miss Laylock on Home Missions

Yesterday afternoon I took the blue-gray socks I had begun to knit, and went over to Sarah White's to sit awhile. She put me in the red-cushioned rocker, and I was real comfortable beside the window, where she had some geraniums that bloomed cheerful-like. We talked about the old days, and had a pleasant time till Celia came in from Topton College. Everything in that kitchen seemed to know she'd come, and peace made tracks for a quieter home. Celia is a soncy-looking girl about 17. She is well up in all the 'ologies, but thinks she knows all creation, and quite patronizes her mother and me. Indeed, I once heard her say to one of her chums that I was "only a back number." I suppose that was one way of saying I am not "up to date." Celia threw her music roll on the floor, her books and hat on chairs, and her rubbers left mud tracks on the clean oil-cloth before she took them off. Then she put her feet up on the front of the stove, while her mother brought her some baked apples to eat, as tea was not quite ready, but she didn't offer to help. I looked my disapproval through my spectacles, but she didn't take any notice; only sat there talking about the college girls, who had pledged themselves to go out to foreign missions when they were graduated, and to go wherever they were sent. Now I know Celia White pretty well; her mother is a widow with two younger children, who are well-known as hard boys to manage, in school or out, for they are very mischievous, and disobedient, but their sister does not try to do any missionary work with them, and only tolerates them when they keep out of her way.

Mrs. White can't afford to keep help, because that girl's college expenses take all her spare money, and yet there isn't a "tea" or any other social function but Celia manages to be there, in a white dress her mother has ironed for her. There is always something to take up Saturday—if not she "studies" in the luxurious college library, and on Sunday she teaches a Chinaman. Some of the girls call her a saint; others envy her fine aspirations, and they tell me she makes a most beautiful prayer at the missionary meetings. But she never hears her little brothers say their lessons, or takes a turn at the dishwashing—all that sort of work spoils the hands. Poor mother's hands!

So she spends her spare evenings in her cosy bedroom, reposing on a sofa among her books, while her mother does the chores, puts coal on the furnace, and if she sits down at all, it is to make or mend for those young people, who seem to think that is all she was made for. To-day she was busy rebinding the frayed edges of a skirt that Celia had worn, and would continue to wear, but for her mother's tired fingers.

"Why don't you let her do that work herself?" I said. "She won't have a dressmaker, or you to fix her up, when she gets out to foreign missions. It seems to me the Lord does not require you to stint yourself like this, and then when Celia is getting able to help you—and get a good situation, to have her go off to heathen countries and leave you to fight it out alone."

"Don't talk about it, please," she said in a faint voice, "I suppose I shall have strength when the time comes. I don't mind a bit about the money and the little stinting."

"No; of course you don't," I added cheerfully, "but it isn't square all the same, and I only hope you'll get your reward both in this world and the next. If that's all the comfort children are after they grow up I'm very glad mine have never been born."

Celia had left the room before I began, but came down when the tea bell rang, looking quite sweet in a newly-ironed blouse that represented hard if loving labor by her mother's busy hands. I saw that Mrs. White agreed with me, though no more was said, for she is of a yielding nature, and her boys have long since found it out. Owen had been kept in after school, and Thomas came home with a black eye, but Celia did not take any more notice of them than if they were two little frogs.

I want to see all nations worship the Saviour, and believe the time is coming when they will, but I like consistency, and have little patience with these unformed girls who imagine they have a calling towards heathen lands, when all they are really trying to do is to escape dishwashing and other irksome tasks at home, and there never was a time when overworked fathers and tired mothers and wayward brothers needed the help of these home missionaries so much as at the present. And even in Bible times just think what would have happened to Lazarus if Mary and Martha had been away on a missionary tour when he took sick? It always seemed to me that the Lord approved of a woman looking after her household, and if He had wanted any of them as an example for the benefit of all Bible readers He would have called one of them when He took Peter and James and John. But then I most forgot we live in the age of the New Woman. ELSPETH LAYLOCK.

Possibilities of a Bean Pot

The bean pot in question came into my possession about a year ago, a piece of Flemish ware whose gray-blue tints and quaint design made it an ornament to the table when a "Boston breakfast" was served in our western household, says a writer in the Christian Advocate. Surely, never were beans more toothsome and tempting than those that came hot and savory on cold Winter mornings from the pot which had been kept snug and warm in the upper part of the big coal heater over night. Some of the possibilities of my treasured bean pot have been revealed to me during the year, which I deem worthy of being made known to other housewives. Perhaps second in importance after its normal function is its use in cooking oatmeal, that delicious cereal which suffers more from undercooking than any of its fellows. After vain efforts to impress upon my maid the necessity of long, slow cooking I bethought me of an expedient which works like a charm. At supper time two cupfuls of oatmeal, four cupfuls of boiling water and a teaspoonful of salt are put into the bean pot and stirred thoroughly. It is then covered and set cooking in the heater, there to simmer until morning, and when the delicate, jelly-like mass is served with sugar and cream, it is a dish that I should not hesitate to set before the immortal old "Quaker" himself, should he drop in unexpectedly.

My bean pot also serves the purpose of a "casserole dish" most admirably and by its friendly aid a tough old hen may be made as tender as a Spring chicken, besides being incomparably finer flavored. (In point of flavor chickens, like good people, "improve with age"). Under its genial influence tough pieces of beef lose their India-rubber characteristics and become masticable. And—crowning triumph of all—consigned to the bean-pot and set in the oven, onions and cabbage may be cooked without advertising the fact in the next block. If one desires to taste apple sauce in its perfection I recommend the following recipe for consideration: Wash and quarter—do not pare—enough red apples to fill the bean pot; sprinkle over a cupful of sugar—more or less, according to the size of the pot—cover and place in the oven on ironing day. Cook three or four hours and pour into a pretty glass dish to cool. The result will be a delicious surprise in the matter of rich flavor and dainty appearance.

In the language of Mr. Browning, "One word more": Press the bean pot into service when you wish to try your hand on that time-honored delicacy, baked Indian pudding—than which there is nothing known to the cuisine harder to bake properly. And by the time you have tried the experiments indicated above I am no prophet if you have not discovered for yourself still other "possibilities of the bean pot."

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

B. T. Babbitt's
Best Soap
is the highest grade, most economical and most satisfactory kitchen and laundry soap.
Made by B. T. Babbitt, New York.
Sold by grocers everywhere.

FAMILY WASHER FREE
ON 30 DAYS TRIAL.
THE "1900" BALL-BEARING WASHER
will do the family washing without boiling, hand scrubbing or back breaking. It revolves on ball-bearings. Simplest, easiest running machine known. No complicated machinery. Entirely new principle. Large quantities of clothes are **washed clean in 6 minutes.** Saving in wear and tear alone pays for machine in a short time.

Convincing Testimony.

Camden, N. Y., June 13, 1900.
I would not take twice what I gave for it. It does the work splendidly. Don't use the board any more.
Mrs. J. Scovill.

Gaines, Pa., Nov. 26, 1900.
I can heartily recommend your Washer as being the best I have ever seen. Don't have to use much strength.
Mrs. C. E. Dimmick.

Columbus, O., Feb'y 18, 1901.
I find your Washer exactly as represented. It is the most wonderful invention of modern times. It is perfect. It is certainly a labor saver and does not wear and tear the clothes. My wife would not part with it for fifty dollars if she could not get another. W. H. Humphries.

Costs nothing to try. Sent to anyone absolutely free for a trial of 30 days. We pay freight both ways. No money required in advance. Send for book and particulars to

THE '1900' WASHER CO.,

BUSINESS BITS.

ZENNER Disinfectant Co., 100 Bates St., Detroit, Mich., has issued a little book, "Dipping Sheep for Profit." It contains the opinion and experience of the best authorities on stock matters in the country. It can be had for the asking by any R. N.-Y. reader.

"JONES, he pays the freight," is a familiar phrase to most readers of THE R. N.-Y. The author of the phrase is, of course, Jones, of Binghamton, N. Y., who is the noted scale manufacturer. He sells scales to the farmer direct, and always pays the freight himself.

DAIRYMEN evidently realize how seriously the flies interfere with milch cows. During the hot Summer months it is impossible for the cattle to do their best when tortured by these blood-thirsty pests. The best evidence of the demand for something to end this nuisance is the way the advertisers are responding. Various smears, liquids and powders are offered for the relief of cattle, and they do their work well. It was a good day for the cow when the wise men started to study out these fly cures.

THE Aspinwall Manufacturing Co., Jackson, Mich., handle a large number of useful devices. Their potato planter is automatic—one man and a team doing all the work of furrowing, dropping seed and fertilizer and covering. The four-row sprayer is another good tool, and the potato sorter does the work of human fingers. There are also churns, domestic tools, post hole diggers, small sprayers, lawn swings, weeders, and other articles in great variety. The colored advertising cards issued by this house are a great feature. It will pay you well to send for them and look them over.

IT is not at all strange that one's mind turns instinctively to the name Studebaker whenever the subject of wagons is mentioned. The Studebaker Bros. Mfg. Co., of South Bend, Ind., have been longer in the business of making wagons than any other firm in the country. In all the long years that the Studebaker wagon has been on the market, it has remained at the top of the now long list of wagons, as to quality of material, workmanship, durability, finish and long continued wear. We need to submit but one instance as proof of Studebaker superiority. We refer to their world-famous slope shoulder spoke as compared with the square shoulder spoke used by other wagon manufacturers. You can see at a glance that the slope shoulder spoke has more wood in it, that it is in no way weakened and that it, and consequently the whole wheel structure, is infinitely stronger. Well, it's just that way with Studebaker wagons all over. It has taken more than 50 years of study, practice and experience to bring about these present perfect results, but the man who buys a Studebaker wagon gets all that for nothing. You may not be able to see it in looking casually at one of these wagons, but it is there as you will realize after using one for 10 years or more. In short, the Studebaker wagon is made in their factory, in their way, with their selected materials, and with their matured experience. Ask at your dealer's or write to the factory. Address Studebaker Bros. Mfg. Co., South Bend, Ind.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

In sudden cases of Croup, and other alarming affections of the Throat and Lungs, Doctor D. Jayne's Expectorant is invaluable. It often proves an elixir of life when death seems very near.—*Adv.*

100,000 POTTED STRAWBERRY PLANTS. Ready July. 49 Varieties. List free T. C. KEVITT, Athenia, N. J.

BINDER TWINE

It affords us great pleasure to quote prices for our famous and well-known grades of binder twine as follows:

Pure White Sisal, 8c per lb. Standard, 8c per lb. Manila, 9¾c per lb.

These prices are for any quantity not less than a 50-pound bale, free on board cars Chicago, and are not subject to discount. TERMS:—Cash to accompany order.

The above twines are our unexcelled "SMYTH" BRAND, pronounced by all who have heretofore used them to be the best in the world. They are prepared with special care from first quality selected hemp, every ball being separately tested for evenness and tensile strength and insect prepared before being allowed to pass examination, hence it is absolutely perfect, is reputed the very best binder twine in the market and we believe it to be worth 2c per pound more than any other binder twine in the market.

WE GUARANTEE our customers against any change in our price and if we go lower, you will be refunded the difference in price. We treat all our customers alike and the early buyer is afforded as much protection as the late one.

SAMPLES FREE. We guarantee our twine, every pound of it, and we will refund your money instantly and without a question if it fails to come up to our representation either in quality or count, but if you prefer to see samples before ordering, then write to us and we will send samples by return mail so that you can see and test it.

JOHN M. SMYTH CO. 150-166 and 287-289 W. MADISON ST. **CHICAGO, ILL.**

If you want a fine imported razor free & 10 cakes of the very best shaving soap in the world, write at once, enclose stamp for sample to Premium Soap Co. Sta. D, N.Y. City. Dept 56

The New Horticulture

BY H. M. STRINGFELLOW.

We do not hesitate to say that this is one of the most interesting books on horticulture that ever was printed. Most reading farmers have heard of the now famous "Stringfellow Method" of planting trees, but few understand clearly what it is. This book tells the whole story in clear-cut, forcible style, which all can understand. Not only is the theory of close root-pruning carefully explained, but the general principles of gardening and fruit-growing are discussed. Mr. Stringfellow is a practical gardener, and he gives his own experience. We commend the book to all without reserve. New Edition, paper covers, 50 cents.

THE RURAL NEW-YORKER, New York.

Market Briefs

PICKED UP HERE AND THERE

ONE SHARPER CAUGHT.—Philadelphia detectives have arrested a commission merchant who, under the name of John Scott & Co., has apparently been doing a wholesale fleecing business. Those in charge of the case claim that they can produce witnesses from eight different States to prove that this man has swindled them out of goods shipped to him. One of the heaviest losers reported is a New York concern, which is said to have been beaten out of $600 worth of eggs. On the letter heads he referred to the commercial agencies. There is a thoroughly responsible house known as John Scott & Co., which has a high business rating, and it would appear that the swindler had appropriated this name, and was doing business on the strength of it. In court he gave a different name, but said that he had been selling goods for a man named Scott who had desk room in his office. His story sounds very "fishy," and it is to be hoped that if proven guilty, he will be salted down to the fullest extent of the law.

EGG QUESTIONS.—A reader asks: "Do commission dealers in New York return empty egg crates or boxes? What is the average commission or margin a commission man would make or charge on a case of eggs (30 dozen)? Would you advise using the old-fashioned cardboard filled case or one of the newer and more expensive kind?" Some commission dealers make a practice of doing a grocery trade in eggs; that is, they sell in small quantities, even lots of a dozen or less. This is particularly the case with fancy eggs. We know of men who sell a good many in this small way at high prices. Buyers often find it hard to get satisfactory eggs from their grocers. They see some man in the market districts who gets a case or two of fresh eggs every day, and are willing to take the trouble of carrying them home at quite an inconvenience in crowded cars, besides paying an advanced price for the sake of getting what they wish. Where the commission merchant empties the cases himself in this way, of course, he can return them to the shipper if desired; but in many instances the eggs are sold in lots of a case or two to retailers; the crates are thus scattered all over the city, and are supposed to go with the eggs. An average commission for selling eggs is five per cent. This is really a low figure when the expenses of the dealer are taken into consideration. He must pay rent and keep enough men to handle a rush of trade, even though on dull days there is but little for them to do. As to whether we would advise cheap or expensive crates, this would depend on the class of trade reached. Some commission merchants who retail fancy eggs have told us that it would be a good plan for the shipper to use a more costly crate. This could be returned, and the eggs show up better than in the rough old boxes which some shippers use. Generally speaking, we think it advisable to use the cheap crates and let them go with the eggs. Some of these empties are saved and gathered up, and large egg men here can often supply quantities of second-hand crates at a low figure. We recently heard of 500 being sold at three cents each.

W. W. H.

GUERNSEY BREEDERS MEET.

The annual meeting of the American Guernsey Cattle Club was held at the Fifth Avenue Hotel, New York City, May 15. The secretary's report showed that the membership had increased greatly during the year, and that the business was in a prosperous condition. Extensive work has been done in rewriting and improving the system of keeping the records. The year was begun with a balance in the treasury of $1,651.90. Receipts were $8,058.35, and expenses $8,629.05, leaving a balance on hand of $1,081.20. Also, $500 has been invested as the nucleus of a fund to provide a permanent home for the club. Plans were made for a union meeting with other Guernsey breeders' associations in this country at Buffalo in September. Reports were made of the results of the home butter tests. To avoid error or deception the cows under trial were tested every month, without previous notice, by State experiment station officials. Following are the figures obtained from these tests for the year ending May 1, single cow class:

E. T. Hill's Glenwood Girl 6th, 9113, 668 pounds of butter. Geo. C. Hill & Son's Primrose's Tricksey, 7236, 592.3 pounds of butter. Geo. C. Hill & Son's Gypsy of Racine, 9639, 504.5 pounds of butter. In herds we have:

E. T. Hill's:

	Lbs. milk.	Lbs. butter.
Glenwood Girl 6th.... 9113	12,184.3	668
Lucretia's Daughter..11256	11,084.6	570.5

Nounon 6569	7,059.5	445.4

Average of the five.....491.58

In the first competition we find Jas. H. Beirne's Lily Ella 7240, 912.5 pounds; Lilyita 7241, 828.95 pounds; Geo. C. Hill & Son's, Countess Bishop 7869, 27.71 pounds; Geo. C. Hill & Son's herd of five cows averaging 454.06 pounds; Levi P. Morton's herd, 450.83 pounds.

Looking at all these records a little more closely we note some interesting comparisons. There are four herds of five cows averaging for a full year from 450.83 to 554.98 pounds, or an average of the four herds of 498.5 pounds butter. There are six cows making records from 504.5 pounds to 912.5 pounds butter, or averaging 672.0 pounds. We also note that two of Messrs. Hill's cows have participated in both competitions and consequently have made two consecutive years' records. They are:

	Lbs. milk.	Lbs. butter.
Lady Bishop for 1899.....	6,868.3	444.6
" " " 1900.....	7,272.4	460.0
Nounon " 1899.....	6,338.0	410.3
" " 1900.....	7,059.5	445.4

In both instances these cows have done better during their second year. This is an excellent illustration of the staying qualities of the Guernsey.

Arrangements have been made for an Advanced Register of animals based on individual merit. Bulls will be admitted for superiority of progeny and cows on milk or butter-fat records. The most careful inspection and tests of these animals will be made by experiment station officials. Cows meeting the following requirements will be admitted to the Advanced Register on payment of the $2 fee for certificate: Milk record as a two-year-old, 6,000 pounds, increasing at the rate of 3.65 pounds per day until it reaches the limit of 10,000 pounds as a five-year-old, or aged animal. The yearly butter-fat records are to be, as a two-year-old, 250 5-10 pounds, increasing one-tenth of a pound per day until, as a five-year-old or aged animal, it is 360 pounds. The seven-day butter-fat record is to be 10 pounds for the two-year-old, increasing .00456 pounds per day until it reaches the five-year, or aged, requirement of 15 pounds.

Also the following prizes will be given for the best butter-fat records for each year ending May 1: For individual cows, $30, $25, $10. For herds of five cows each, $50, $30.

The officers elected were: President, James M. Codman, Brookline, Mass.; vice-presidents, H. A. Cassatt, Pennsylvania; Henry Sydney Fisher, Minister of Agriculture, Dominion of Canada; secretary and treasurer, William H. Caldwell, Peterboro, N. H. Members of the executive committee for four years: N. K. Fairbank, Chicago, and Howard B. Tuttle, Naugatuck, Conn.

FARMING IN MEXICO.

What do you recommend as the best thing to do in farming on a small scale in Mexico, and what locality do you think best? W. H. J.

Tenango, V. C., Mexico.

I take it that W. H. J. wants to know what kind of farming on a small scale is the best, although you ask me concerning the "best methods." In regard to best methods, I should say that the methods adopted by the leading agriculturists are the best, although they may have to be modified somewhat according to local conditions. The underlying principles of agriculture are certainly the same in all quarters of the world, and so if I intended to go into truck farming in the tropics I should proceed in exactly the same way as I would in the north. If I bought a piece of virgin forest land I could not, however, begin clearing with an ax. At the beginning of the dry season the underbrush and vines are cut down with a machete (cutlass), then all the smaller trees are cut down, and lastly the remaining large trees are felled. In order to insure good burning all large branches which stick up in the air are now cut off, and at the end of the dry season the land is burned over. If it is desired to plant corn, that can be proceeded with immediately. By burning the land over several times in succeeding years it is finally cleared of all trunks, stumps, etc., but if it is desired completely to clear the land the first year, it would be necessary to employ several teams of oxen and a stump puller, in order that the larger trunks and stumps may be got rid of.

Planting can be done all the year around, even during the dry season, if means for watering are at hand. Here, however, the regulation methods of the north may be modified. During the rainy season seeds need not be covered, or else should be covered only lightly with earth. The natives plant corn by making a hole in the ground with a pointed stick and dropping in from five to six seeds. The holes are left uncovered and the corn grows very well, securing a deep hold on the soil, because the holes are made about eight inches in depth. Nursery stock is often set out in the same way. The plant is placed in the hole and then a little earth is forced against it with the same pointed stick.

We can go Mr. Stringfellow one better down here. Mr. Stringfellow root-prunes his nursery stock to a stub, while we can take a stocky young plant, cut it off just above the roots, use it as a riding whip for a day or two, and then stick it into the ground with the full assurance that it will grow with a nice bunch of short roots all around the base of the stem. I have seen fence posts sprout and branch which were set a month after they were cut. It seems to me, then, that the "Stringfellow method" is merely a question of latitude. Prof. Bailey has shown that pruning the roots to a stub is not adapted to New York, and the same holds true for all the Northern States. The Southern States can prune the roots to a stub, and in the tropics we can cut them off entirely, although that may not be advisable. Since, then, the foundation of Mr. Stringfellow's system cannot be carried out in the North, how is the rest of the system going to be carried out? Mr. Stringfellow argues in favor of natural methods, and he himself adopts a method more artificial than any yet devised. Is confining the roots to a few feet of space and pumping fertilizers on them a natural method? What is the aspect of that "mammoth peach tree" cited by Mr. Stringfellow? I wouldn't be surprised if it is at the foot of a slope leading from the manure pile by the barn. If not, then I'd like to have Mr. Stringfellow trace out some of the larger roots and see where they run to. Here he could study natural methods. The "Stringfellow method" is all right in its place, and it is even better adapted to the tropics than it is to Texas, for besides conditions more favorable to plant growth here, there is also the labor question, the natives not knowing how to use modern farm implements, which, of course, are not necessary if only a few feet around the trees is to be cultivated.

To get back to the original question: If your subscriber has not much capital it seems to me that the best thing he could do would be to raise vegetables, pigs and chickens near some growing town, and if he wishes, he can at the same time plant some crop from which he can get returns in later years. For instance, he might locate five or six miles up the Coatzacoalcos River and take his vegetables, chickens, eggs, milk, etc., to Coatzacoalcos to sell. Milk brings 25 cents a quart, eggs two to three cents apiece; chickens, 50 to 75 cents; vegetables are proportionately high, and lard always brings a good price. (Prices in Mexican currency). As a side planting he might set out vanilla, which bears in three or four years, and is a very paying crop. Labor is worth 62½ cents a day, or else 50 cents and rations. As to other locations I cannot say much, but think that Salina Cruz, the other terminus of the Tehuantepec railway and Tampico would also be good. H. L. T.

Coatzacoalcos, V. C., Mexico.

SCRAPS.

We receive frequent questions about the value of spent tan bark as a fertilizer. The chemists place little value on it, though the ashes from burning this bark are useful. Some practical farmers have reported good success where the spent tan was used for mulching currants or other bush fruits.

The cherry and pear trees are blossoming freely, and not much difference in the variety. I think the old-fashioned black cherry is not quite as full of bloom as the sour cherries or the Yellow Spanish. The pears are loaded with buds and blossoms without much distinction. Peach trees are also well in blossom though not as full as last year. J. T.

Ira, N. Y.

The hamster, a small rat-like rodent, is causing great damage to agriculture in central Germany and the eastern part of Belgium; it is migratory, and is regarded as such a source of danger that the French agricultural department is offering a bounty for its destruction. In some parts of Europe it appears to be as great a danger as the gopher in the Western States.

A Manure Cellar.—Replying to W. B. W.'s inquiry on page 356, about cement cistern for manure drainage, my advice is not to make one. He will not find any draining from horse manure; rather, it will be too dry. I would recommend cementing floor of manure shed, making it lower in center. I once made a cement cistern in bottom of my manure cellar where I kept cows, but after a few years' trial I filled it up. It proved of but little utility and was much bother. M. Morse.

Dizziness

Is a very common consequence of indigestion and torpid liver. Sometimes there are spots before the eyes and hot flashes. At other times a sensation as of vertigo occurs, at once suffocating and blinding. It is a waste of time to attempt to cure this condition by ordinary means or medicines. The stomach and organs of digestion and nutrition must be restored to healthy activity, the blood must be purified, the liver cleansed and strengthened, before a cure can be hoped for. This is the work done by Dr. Pierce's Golden Medical Discovery, a medicine specially beneficial in diseases of the stomach, blood and liver. It strengthens the stomach, purifies the blood, cleanses the clogged liver, and promotes the health of every organ of the body.

"My wife was greatly troubled with indigestion, torpid liver, dizziness, and also irregular periods," writes Mr. W. A. Preston, of Shuqualak, Noxubee Co., Miss. "We tried many different remedies, but none of them gave perfect relief until we were induced by a lady to try your 'Golden Medical Discovery,' 'Favorite Prescription,' and 'Pleasant Pellets.' These medicines did more good than anything we ever tried for those complaints. We have used four bottles of your 'Golden Medical Discovery,' one of 'Favorite Prescription,' and two vials of your 'Pellets.' These medicines have done the work we desired, and I do heartily recommend them to all similar sufferers."

Dr. Pierce's Pleasant Pellets assist the action of the "Discovery."

RUBEROID

THE

POULTRY-HOUSE

ROOFING

As a water-proof covering for Poultry-Houses, RUBEROID has no equal. Keeps the houses cool during the warm weather, and warm in Winter, and the chicks dry and comfortable. The sun cannot melt it.

DAIRY AND FARM NOTES.

Tenant System and Dairy Farms.

RENTING THE HOME FARM.—The tenant or renting question interests me much. We have tried it, and have one farm rented at the present time. Farms cannot all be worked by their owners. After a man and his wife have paid for the farm and raised a family they feel it is time to rest. This is right if some younger member of the family would assume command. But here is the rub. The parents, feeling keenly the necessity of hard work and economy in order to make payments and a living, worked early and late; went without many little comforts of life that the neighbors enjoyed, or thought they did. Their ambition was keyed up with a determination to win, and they did. After the battle was over the excitement was gone, and they justly decided not to enter another race that they might not be able to finish. How easy it is to see that the young people, not imbued with that same ambition, and having been brought up under a sacrifice, or in other words having seen what it costs to win, say to themselves: "I guess not; I don't propose to tie myself to a cow all of my life as my parents have done. I'm going to do something easier!" The parents, feeling the cost of their farm and home in hard work and sacrifice, are inclined to let the children go where they will, not requiring them to work so hard, and they are soon away, with a boast from Father and Mother that John or Mary has been very fortunate in securing a clerkship or some duty akin to it, and finally the old people are influenced to follow the children to town, and the farm is rented. In most instances under my observation from this date begins the decadence of that farm.

SUCCESS THROUGH HARD WORK.—The debatable point here is whether or not these people really did spend more vital force and energy, endured more hardships, or practiced more rigid economy than people who succeed in other fields of labor and activity? As we read the history of successful men and women, of it is all written the same story of self sacrifice, hard work, indefatigable stick-to-itiveness and disregard of the eight-hour law. Any farmer boy who thinks his lot is undeservedly hard should read "The Making of an American," by Jacob Riis, now running in the Outlook. Of course there is always a disposition to look at things from a selfish or partisan standpoint, but a judgment formed in my calmest and fairest moments has been that farmers who succeed as a whole had no more enemies to fight, battlements to scale or chasms to bridge than other people. The conclusion therefore of this young man with the moral support of his parents was drawn from a narrow conception of the world and things in it. He forgets that when he leaves his home he must begin just where his parents did, at the foundation, while the boy who takes up the farm work of a successful father really, all other things being equal, has one generation the advantage. Yet we all know how few succeed who do not in some way help to lay the foundation themselves. It's the fellow who does the thing, and not the fellow who talks about it, who knows.

THE RENTING SYSTEM.—Our theorizing about causes will not help out a solution of the renting system. At Washingtonville, Orange Co., N. Y., last Winter at the first session of the institute, Hon. C. P. Goodrich, of Wisconsin, was to give his valuable lecture on the dairy cow. The attendance was so small that Mr. Halleck, the local correspondent, very tritely remarked that it would be better for me to talk for a time, if the session must begin, than to waste Mr. Goodrich's valuable address on so small a crowd. I fully appreciated personally the force of the observation, and under some embarrassment began to kill time and without previous thought drifted into a discussion of the renting system. Comparison cannot be made between renting and living upon a farm where a great portion of the work is done by the members of the family. A man who cannot make his farm profitable himself will never succeed in renting it, asking the farm to support two families instead of one. Comparisons must be made between hiring the work all done at a fixed wage per month, and share or cash rental. We find the greatest difficulty in renting is to keep fertility and general conditions improving without doing a good deal of work ourselves. A well-tilled and productive farm rented for a couple of years is much like renting a store full of goods and not requiring the inventory at the conclusion of the term equaling that at the beginning. There will be found a little less of everything—the tenant having taken the profit, and then one must work two years to get his stock reënforced. When men work by the month or year they fail to feel the necessity of frequently cutting the corners and doing only the things that count, as a man will do who depends upon the income from the farm for his support and profit. I am speaking of a first-class tenant, and we have one of this sort, not the professional renter who stays one year and sometimes more, and then moves to new fields. He is remembered, often on the books of the local tradesmen.

THE LABOR SYSTEM.—In working, as we are doing, three farms by paid labor, we are able to give something like a personal supervision. We hire a foreman and his wife, who have immediate charge; yet a personal every-day supervision is possible. Our balance sheet does not materially differ under the two systems so far as cash returns and expenses are recorded. But a final balance is in favor of the labor system, because improvements go hand in hand with everyday work, while a day of reckoning frequently comes on the tenant farm calling for the returns that at one time seemed all profit. If the owner is to reside in town, away from the farm, unable to throw his personal force into the work, he would better adopt the renting system. Then again, results will depend upon one's ability to direct labor. I know of farmers who never get good men, and usually in their lifetime every man within 20 miles has worked for them. Other farmers always get good help. The discussion at this meeting followed along about the way I have written it. I gave them some figures made last year on a farm which had been rented until it paid no profit at all. The first year a profit of five per cent was obtained, and we grew double the stuff formerly grown. The foreman, however, is an active hustling young man, who makes things go. W. H. Halleck, a thorough-going business farmer, who owns and manages under the labor system 150 cows, practically subscribed to these points as I gave them, saying: "He could have things done as he wanted them," but this man knows how to handle labor. There is another phase to this subject. The owner, when he moves into town, is apt to become a kicker. He is out of his proper sphere. He is earning nothing, so of course feels the urgent need of economy, and knows no way more effectual than protesting against every improvement. If he goes into business at his age, and without mercantile training, failure is quite sure to follow in competition with old experienced houses that enjoy the fun of squeezing him occasionally.

In conclusion, let me urge the wisdom of living upon the farm. Invest the surplus in improvements, instead of a mortgage upon another farm. Make it a home in the full sense of the term. It will be just as attractive as a village home, both for you and your family, who will be willing to stay there and work it. Take the boys into partnership. One-half the money required to start them in business will hold them to the farm, provided always they have an inclination and adaptability. This will be one way to solve this perplexed renting question that is a bar to agricultural progress wherever it has been my opportunity to observe. H. E. COOK.

A Bunch of Beef.

The picture (Fig. 158) shows a bunch of beef cattle in an Oklahoma pasture. These animals are "ripe"; that is, ready to be shipped east to the great slaughter-houses. They are all dishorned as most beef cattle are in these days. Bunched up against a barbed wire fence they certainly form a picture of contentment. Oklahoma is becoming noted as a grazing and feeding country. The pastures are ample, and great quantities of corn, Alfalfa and Kaffir corn are produced for feeding. At present beef prices these crops sell well when packed into the carcass of a well-bred steer.

Ailing Animals.

ANSWERS BY DR. F. L. KILBORNE.

Heifer Fails to Breed.

I have a heifer coming two years old. I have never seen her in heat yet; is it best to keep her longer? A. W. H.
Windsorville, Conn.

Turn the heifer to pasture, and feed no grain whatever. If she does not come in heat in four to six weeks, she will probably never do so, and it would not be advisable to keep her longer.

Horses Out of Condition.

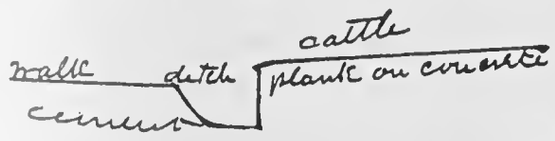
I have a mare 11 years old. She has been out of condition since last October; her coat is rough and body thin; eyes dull, and she has a poor appetite. She lies down at night as usual. I work her hard at present. I have fed various kinds of condition powders, carrots and potatoes, but all have failed. I feed her oats, bran and corn and a little upland hay. What can I do for her? J. B. G.
Echo Lake, N. J.

Try the following course of powders: Powdered gentian and nitrate of potash, of each eight ounces; sulphate of soda, 16 ounces; powdered nux vomica, four ounces; mix and divide into 32 powders. Give powder in feed twice daily. Allow a short run on pasture if you nave the opportunity.

Hernia or Breach in a Heifer.

Would a yearling helfer with a small breach of three weeks' standing, otherwise healthy and fat, be wholesome to eat for beef? Would she come under the class of diseased animals? Breach did not come through the hide and no local inflammation. R. W. W.
Jasper, N. Y.

A small breach or hernia, on an otherwise healthy animal does not render the flesh unwholesome for food. If there was strangulation of the bowels, sufficient to render the animal feverish (which would be shown by the animal being in pain) the flesh would not be wholesome, as the flesh of any feverish



CEMENT FLOOR IN COW BARN. FIG. 162.

animal is not suitable for food. A heifer in the condition you describe, if she were not feverish, would be perfectly wholesome for food, and you would, in my opinion, be justified in butchering and selling her for beef.

Skin Eruption on a Horse

I have a seven-year-old driving mare that is rather thin in flesh. She has plenty of life and is a little nervous. I think she either has some skin disease, or her blood is out of order, as she has little bunches about the size of a buckshot all over her, and she is covered with dandruff. Apparently she also has indigestion as she has frequent movements of the bowels. I feed her 10 quarts of grain a day; do not drive her more than enough for exercise.
Chester, Conn. H. J. L.

Give the mare (if not in foal) one ounce each aloes and ginger, either in ball or by drench in one pint cold water. Follow with one of the following powders in her feed twice daily. If the bowels become too loose discontinue for a day or two: Sulphate of soda, 16 ounces; nitrate of potash and powdered nux vomica, of each four ounces. Mix and divide into 16 powders. If the mare refuses to eat the powder, give in half-pint water by drenching.

Garget in Cow; Horses Out of Condition.

1. I have a cow subject to garget; her udder swells and cakes at calving time. How shall I treat her? 2. My horses keep rather thin in flesh. One is hidebound and thin, weight 1,125; sweats easily; eats well. The other, a mare, is a greedy eater and drinker, but does not gain well, weight 1,150. Grain four quarts ground oats, 1½ quart cracked corn, two quarts shorts at a feed; work every day. Please prescribe for them. F. C.
Cumberland Co., Me.

1. Whenever an attack occurs, bathe frequently with hot water or rub with hot oil several times daily until the congestion is relieved. Milk out dry each time. Internally, give one to two pounds (according to size and condition of animal) Epsom salts at the outset, and follow with a laxative diet. Also give 25 drops tincture aconite and one-half ounce nitrate potash in half pint water, and repeat every six hours. 2. Give one of following powders in the feed twice daily: Powdered gentian and ginger, of each 24 ounces; powdered nux vomica, six ounces; arsenic, 120 grains; mix and divide into 48 powders.

Horse Subject to Colic.

I have a horse that is five years old and is subject to the colic. Is there anything to feed him to prevent such attacks?
Waterloo, N. Y. H. E. S.

There are a great variety of cases and several forms of colic; and without knowing the cause I cannot advise a course of feeding to prevent the attacks. I can only suggest that you take the horse to a competent veterinarian for a personal examination, to ascertain the cause of the trouble.

Epileptic Fit in a Horse.

1. I have a horse eight years old, weighing 1,500 pounds, that was bitten by a dog a year ago. A month ago he had a spasm; muscles quivered and jerked; eyes were like balls of fire, and bloodshot; nose red and widely expanded; breathing hurried; frothed at the mouth, and kicked and snapped at everything in reach. Afterward a cold sweat came out all over him. A veterinarian gave him Spanish fly and chloral, and after 48 hours the horse seemed to be as well as ever. Was it rabies, and is it likely to return? Would it be safe to work him? 2. What is the best remedy for thrush in a horse's hind foot? W. A. W.
Allegheny Co., Pa.

1. The symptom you give indicate an attack of epilepsy. It evidently was not hydrophobia or rabies. The attack may or may not occur again, depending upon the cause. I would advise working the horse moderately, at least, until he suffers another attack. 2. Pare away all dead or diseased horn, and apply dry calomel, repeating the application daily until the discharge ceases.

A Cement Stable Floor.

Just a few words in regard to cement floors in cow stables, as inquired about by J. C. L. in THE R. N. Y. of May 11. We have had them in use for many years, made by the help employed on the farm alone, and they have given entire satisfaction. The floor is shaped just as in the rough diagram, Fig. 162. The part on which the cows stand is of plank in one and of one-inch pine boards in the other, laid on concrete, with a chestnut sill at the rear to spike to. In one stable finely-broken stone was used for base, filled in with soft Rosendale cement, and finished with about an inch of Portland. The other stable, done later, was cemented almost entirely on the hard-tramped earth, and answers just as well as where laid on broken stone. Of course the bed was shaped out first. Both are just about as solid as stone. Though not practical mechanics, we had no trouble whatever in making the curves of the gutters with a common mason's trowel. The cattle are fastened in pivoted stanchions and the floors are of a length to suit the kind of cattle kept. The gutters are from 18 to 20 inches wide and the walks four to five feet. Any men with fair intelligence can do the work. We used two parts of good cement to three parts of clean sand. WM. T. SMEDLEY.
Clinton Co., Pa.

A HEN RECORD.—Record of the number of dozen eggs sold from a flock of hens of about 150 in number from January 1 to December 31, 1900: January, 145 dozen; February, 134; March, 135; April, 220; May, 280; June, 168; July, 105; August, 99; September, 45; October, 47; November, 25; December, 76. About September 1, 71 hens, or about one-half of the flock were sold to the butcher; this accounts for the great falling off during the rest of the year. The above does not include the eggs used in the family or for setting. The hens are of all breeds, something like Hope Farm fowls, and I would like to know whether my flock will compare favorably with those of that celebrated institution. These eggs are sold every week to a grocer in a nearby city at two cents above the market price, and in more than two years not one bad egg has been found. L.
Connecticut.

—DE LAVAL—
CREAM SEPARATORS

Great as has been the previous superiority of the De Laval machines to other separators, the latest 20TH CENTURY "Alpha," developments place them still further beyond the possibility of attempted competition from anything else in the shape of a cream separator.

MAY, 1901, STYLES, CAPACITIES AND PRICES:

Old Style "Strap" Humming-Bird,	175 lbs.,	–	$50.00
Improved "Crank" Humming-Bird,	250 lbs.,	–	65.00
Improved "Dairy Special,"	325 lbs.,	–	85.00

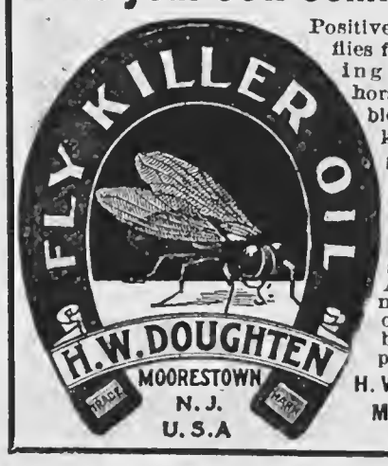
Make your Cow Comfortable



Positively prevents flies from annoying cows or horses; rids stable of flies, keeps stock good tempered and in fine condition. A boon to every stock owner. Apply to your nearest dealer or write for booklet and prices.
H. W. Doughten, Moorestown, N. J.

Shoo-Fly THE ANIMALS' FRIEND

Kills every fly it strikes. Keeps off the rest. Harmless to man or beast.

This cow was a terror to milk prior to using ½ cents worth Shoo-Fly. Had it been used earlier she would not have lost milk and flesh to the amount of $14. The other cow was protected early and continued to give 18 qts. daily through fly time. Thousands have duplicated 10 gallons seven consecutive years. If your dealer does not keep it, send us $1.00 for latest improved double tube sprayer and enough Shoo-Fly to protect 100 cows, or send 25c for liquid. Cash returned if cows are not protected.
SHOO-FLY MFG. CO., 1005 Fairmount Ave., Phila. Pa.

THE CHAIN-HANGING
Cattle Stanchion
The most practical and humane Fastener ever invented. Gives perfect freedom of the head. Illustrated Circular and Price free on application. Manufactured by O. H. ROBERTSON, Forestville, Conn.

Wilder's Stanchion
—being an improvement over Smith's. Lightest, strongest, quickest, safest swing stanchion made. Has steel latch and automatic lock. Becomes stationary when open. Animal cannot turn it in backing out. Made of best seasoned hard wood. Pins for fastening with every stanchion. Send for testimonials.
J. K. WILDER & SONS, Box 20 Monroe, Mich.

The New Improved
EMPIRE
Cream Separators
are now ready for the trade. They have proven a marvel in Cream Separator construction and results attained through their use astonish experts and appall all competitors.

The Empire No. 1
has a bowl weighing only 4½ pounds, only 2⅝ inches in diameter, only 4⅛ inches deep with only four parts to the skimming device and with a skimming
Capacity of 250 lbs.
per hour. Never before was a separator bowl of such size known to handle this quantity of milk successfully. On account of being so light, it is easy to turn, easy to handle and so simple it is easy to clean. Machines of greater capacity are equipped with bowl of comparative size. Our new catalogue tells about them and contains much of interest to you. It is free. Send for it.
United States Butter Extractor Co., Bloomfield, N. J.

ROUND SILO
THE PHILADELPHIA.
The only perfect continuous open-front Silo made. See Open-Top Patent Roof. Ask for catalogue. E. F. SCHLICHTER,

COW HORN TURNIPS AND CRIMSON CLOVER

HOW THEY ARE USED AS GREEN MANURE.

Farm Practice of a Pennsylvania Farmer.

On page 286, Chas. Johnson gave a brief report of an address delivered at a Pennsylvania farmers' institute by R. S. Seeds. This has called out so much inquiry from our readers that Mr. Johnson has prepared the following fuller report of the lecture. The result with oats during an exceptionally dry season is worth noting:

HARD SOIL, NO MANURE.—"The value of fertility and the cheapest way to get it." Under this title, Mr. Seeds, a practical farmer living in the Juniata Valley, discussed, before the Monroe Co., Pa., Farmers' Institute, the method by which he had succeeded in restoring a "rundown" farm. The farm on which Mr. Seeds commenced operations seven years ago had been managed in the usual way for presumably 50 years. It was then rented for a number of years, until no one could be found to rent it. Then the practice of working it on shares had been tried until about 14 years ago, when it passed into the hands of the mortgagees. From this time until sold to Mr. Seeds the place had been practically abandoned. The soil is a strong clay loam, and seven years ago fell with a dead thud immediately after leaving the plow. At that time four inches was as deep a furrow as could be turned, and that only with difficulty. The experiment of hauling stable manure from the neighboring town was tried, but found too expensive, necessitating an outlay of from $20 to $25 per acre. A little computation soon showed liming to be impracticable for the same reason. Since no money could be spared for manure or fertilizers, some other means had to be devised to make this hard, compact soil productive in any degree.

DEEP-ROOTED GREEN CROPS.—The most natural solution of the problem appeared to be green manuring. Literature on the subject was collected, and plans formed for the season's work. The first crop used for this purpose was Crimson clover. This experiment proved unsatisfactory. Several reasons were given why a good stand of clover was not obtained, viz., failure to cultivate the seed in, the use of southern-grown seed, and the uncongenial condition of the seed bed. Then, too, Crimson clover was objectionable because of the long season necessary for it to reach maturity, thus delaying the use of the land in early Spring. Furthermore, it grows "on top of the ground," and consequently does not loosen up the subsoil as much as seemed desirable in this case. A plant with a long root that would mature in the Fall, was sought for but not discovered in time for use the following season. To supply the need the second season, the Purple-top Strap-leaved turnip was used. The objection to this was that it also grows "on top of the ground." The objection so often heard against the use of this class of cover crops, that *they take moisture from the soil when it is needed to mature other crops*, Mr. Seeds does not regard as warranted, since the ground, where shaded by the turnips, showed more moisture on the surface than could be found elsewhere, while the corn matured a heavy crop of both ears and stalks. It was not until the third season that the Cowhorn turnip was used. The first lot of seed was obtained from a western seedsman, but most of the leading seed merchants now catalogue this variety. This plant possesses most of the qualities desired. Photographs taken of specimens in the field, both in the ground and out of the ground, show it to be a rank grower and deep rooter. Mr. Seeds assured his audience that individual specimens measuring nearly four feet were found, while a length of two feet four inches was quite common. In order to dispel any doubts in the minds of the incredulous, Mr. Seeds added, that he always meant "tops and all." Fully one-half of the growth, as shown by the photographs, was below the surface of the ground. These crops are grown in the cornfield and left there after the corn is taken off. No attempt is made to harvest them or to use them for any other purpose than soil improvement.

RESULT IN OATS.—Among the photographs exhibited at this meeting was one of a field of oats. This field had attracted attention during the earlier part of the season, because of its peculiar dappled appearance. "To the casual observer it was evident," says Mr. Seeds, "that the dark spots were by no means accidental, because they occurred at regular intervals, and were of practically the same size." An examination showed that the spots occurred just where the corn shocks had stood. It had been noticed in the Fall that where the corn shocks had stood the growth of the turnips had been checked, and in many instances decay had set in, while the surrounding plants continued to grow for a month after the corn was cut. The stronger growth of the oats was attributed to the greater amount of available plant food in the soil consequent upon the more complete disintegration of the vegetable matter beneath the corn shocks. This field of oats was the only one in the Juniata Valley, according to Mr. Seeds's statement, that more than paid expenses in the year 1900, "the driest season" ever experienced in that section of the country. Other photographs shown did credit to the cultivator, whether in the Juniata Valley or elsewhere. Crimson clover waist-high, Red clover nearly waist-high, measured by Mr. Seeds as a standard, and as heavy as could be desired certainly need no description from me. A good stand of Alfalfa has also been obtained after repeated trials. The mistake made on this crop was in attempting to seed it the same as clover, instead of treating it as an independent crop.

BURBANK PLUMS IN A POULTRY YARD. Fig. 163. See Page 406.

TURNIPS AND CRIMSON CLOVER.—Mr. Seeds no longer uses the turnips alone, but uses them in connection with Crimson clover, sowing one pound of turnip seed and one-half peck of Crimson clover seed per acre. When used alone he doubles these amounts. Both kinds are sown at the last cultivation of the corn, and cost no extra labor except that necessary to sow the seed. Among the plants he will try this season are the Sand vetch and cow pea. The crops of Cowhorn turnips are turned under in the Fall, when possible, in order to aid decomposition and render them more available for succeeding crops. The Crimson clover is turned under any time after it has made a fair amount of growth. By this means Mr. Seeds estimates, from analyses given by the New Jersey Experiment Station, that he is plowing under about $50 worth of fertility in the shape of potash, nitrogen, etc., costing in the year 1900 only 54 cents per acre to raise. In addition to this, his soil has become lighter, works easier, holds moisture better, is cooler in Summer, warmer in Winter and can be worked earlier in the Spring.

As evidence that his improvements are genuine, Mr. Seeds made the statement that the valuation of his farm had been increased $25 per acre in three years. He now experiences little difficulty in handling the ordinary farm crops, and is satisfied with the results obtained.

CARING FOR MANURE.—At a later session of the institute Mr. Seeds explained his method of caring for his barnyard manure and disposing of it. The barnyard has been made practically a part of the barn by putting a roof over it and walling up the sides. Windows are provided to admit light. The center is hollowed out and puddled with clay. All drainage from the stables is saved, and the manure is hauled out in Winter on the grass, from which hay is to be cut the following season. Mr. Seeds dislikes the practice of hauling manure out on corn land because it does not give results until Fall. The greater portion of the fertilizing elements is washed out before the crop can make use of them. Then, too, he claims that manure not thoroughly composted, when applied to crops other than grass, has a tendency to favor drying out, and thus may prove injurious rather than beneficial.

CHARLES JOHNSON.

Cape May Co., N. J.

RENTERS AND RAIN.—We are renters, and can see many dollars of hard work wasted on undrained places, wasting of feeds and liquid gold running from barnyard, but have been unable to get the owner to see it, so it continues to go on, and this extra wet Spring shows things off, and nearly makes us discouraged. May 24 was the storm that capped them all. Old men say it was the worst one of their time. Oat seeding was cut short 12 or 15 per cent, and much of the seed in is being washed out. A very little corn is planted, and a good many have not plowed a furrow. There has been considerable hail, but have not heard of all the damage. Many bridges were washed away, and some hill roads are nearly impassable. More rain to-night; no corn or potatoes in in May. Pastures are good but hay seems to stand still. As for anything new about milk, there is nothing, only the new milch cows, and the new names going on the tally sheet. Milk at 60 cents per can, 40 quarts; the dealer skims milk and sells back to the farmer, one farmer getting a pound of butter per can of skim-milk, but a new separator is to go in in a few days. Such are the profits in the milk business (one-sided). W.

Bradford Co., Pa.

R. N.-Y.—Similar weather conditions are reported from so many sections that we think early crop reports will be subject to decided revision, especially as regards fruit and grain.

TRIMMING VARIETIES OF BLACKBERRIES.

One of our readers says that in trimming blackberries one must be careful not to prune Early Harvest severely, because, he says, the fruit buds of that variety are chiefly borne near the end of the canes. He says that other varieties may safely be trimmed severely, but that Early Harvest should not be handled in this way. This leads us to think that possibly there may be differences in the growth of small fruits which require special care in pruning. Is it safe to give general directions for trimming or pruning bush fruits generally, or do the varieties have such difference in growth that we should change our methods according to the variety?

I do not doubt but what your reader is right about pruning the Early Harvest blackberry. While I have not observed this peculiarity that he speaks of in this variety, I know that different kinds of raspberries make different growths, so that they receive different treatment in the hands of expert growers. These differences in growth and bud formation can scarcely be called a varietal characteristic, but rather a characterlstic of the race or type of fruit to which the variety belongs. These differences are usually not apparent to the ordinary grower, but in some instances these little features are taken advantage of, and the knowledge is turned to good account. The following extract from a letter from Mr. J. F. Hunt, one of the best small fruit growers in central New York, shows that different types of raspberries need different treatment in order to get the best results, and also I think that there are many things in small fruit growing that escapes the notice of the majority of men:

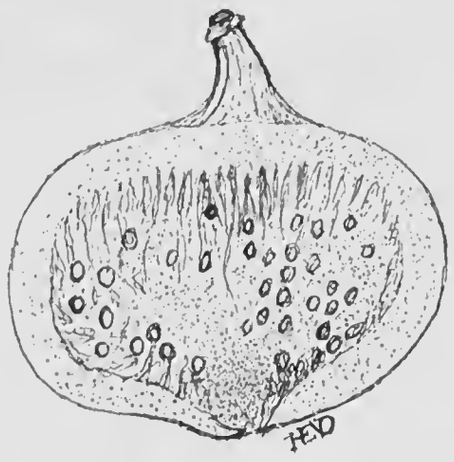
"Would say that my experience in trimming the Shaffer berry is very much the same as in trimming blackcaps, except trim shorter, as each well-developed bud has the capacity of producing twice as many berries as buds of blackcaps with the same development; that is to say, if each was forced by proper trimming to its full extent. If the new growth was pinched off when about 12 to 15 inches high, making the head low, the pruning of side branches may be longer than where the head is high and the weight of the berries tops the bushes over on the ground, and nearly all of the fruit is lost on account of being covered with dirt. I believe I have learned this, that three or four canes to the hill, cut very short, will produce more fruit in a dry season than the same canes trimmed long, or more canes left in the hill. If there is too much wood left to set fruit, and a heavy crop develops, and conditions are unfavorable, then the whole crop is forced to maturity in a few days. On the other hand, if cut short, the least-developed buds on sides of main cane start late, and so lengthen the season by a week or more. The same conditions I find hold true with the Cuthbert berry, but not with blackcaps to any extent. With blackcaps, such varieties as Ohio, Palmer and Souhegan, that have short-jointed wood, should be trimmed accordingly; they also develop many more berries to the bud than the Gregg and that class of berries." W. PADDOCK.

WATER WORKS FOR THE FARM.

I have been interested in what the Hope Farm man said about his water works, because I put in some last Fall myself. I built a cistern that will hold 170 barrels, in the top of the hill south of the house—grout and cement wall; 15x6 feet, eight feet deep. The top of wall is six inches above surface of ground, and cistern has a frostproof cover. It was a back-breaking job, digging the ditch and cistern; had to use a pickax all the way (38 rods), and near the cistern the ditch had to be eight feet deep, so I can draw right from the bottom. No siphon business for me; a siphon will work all right—for a while, and the bother begins. Fig. 165 shows how I have my water works arranged; two hydrants in garden and one each in flower garden, barn and pigpen; three valves in barn and two in house—one in kitchen and one at Cooley creamer. I have three way cocks in well, so I can either draw from cistern or pump from well. I can attach hose at pump or flower garden hydrant, and throw a stream over the house. I have a hydrant by the stable door (inside) where I can water the horses; and the pipe then extends to the top of the stable room, and from there all the way on a slant, out through the cow barn in front of the cows, to the water trough in barnyard, so I can drain the pipe out and have no trouble with zero weather. There is a feeding alley in front of horses, where cut hay drops down from above; have a mixing box there and a short hose, with the ground feed just a step from it; so everything is handy for giving the horses their mixed feed. I put cement on one end of the bottom and part way up on the sides of the alley in front of cows, and use that to mix the cut stalks and feed for the cows; of course I have a hose there.

My wife appreciates the water as we have it now, but she will have it still better when some changes are made in the kitchen and a bathroom added, for then with a water front in the stove she will have both hot and cold rain water and cold well water; can make the windmill pump up the rain water, too. The boys think the cistern is a mighty fine thing, too, because now they never hear: "Come boys, fill up that trough!" You know the old saying: "You can lead a horse to the water but you can't make him drink!" I can do better than that, because I can stick the hose down his throat and make him drink.

I have been trimming a young orchard set out four years ago. In spite of the fact that when setting them out I leaned the trees slightly to the west, many of them are now leaning to the east, and many of the limbs on the west side are bowed right over to the east. Some of the Roxbury Russets were and are of fine shape, but some of them were crooked, and despite careful pruning are so still. I think they must have crooked blood. Rome Beauty, Jonathan, Spitzenburg, Wagener and Grimes Golden will bear this year. The present prospects for all kind of crops are good. Red clover that I sowed in Spring wheat April 27 is better than that I sowed on Winter wheat April 6. J. R. W.

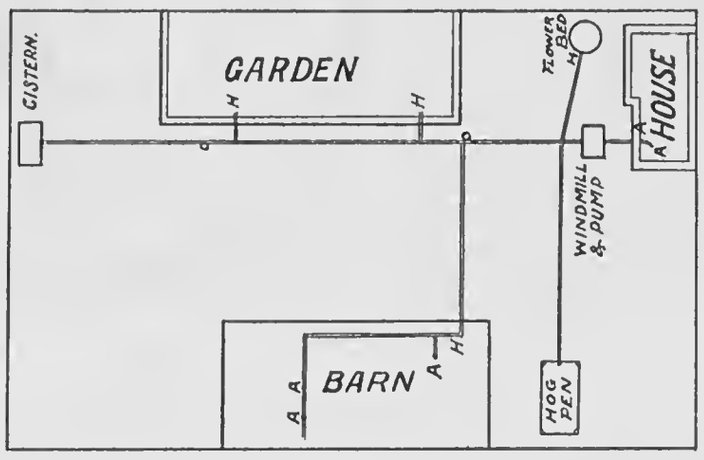


SMYRNA FIG FROM CALIFORNIA. Fig. 164.

Shortsville, N. Y.

NOTES ON STRAWBERRY GROWING.

Many authorities on strawberry culture advise plowing up old beds after the second year and starting new ones. Some suggest cleaning out and working over old beds without moving the plants, but I have found this practice usually labor lost. The roots of the strawberry begin to decay when the fruit matures. All the strength and vigor of the plant passes from the roots to the berries and runners; consequently the old root system becomes enfeebled and gradually withers and dies. My own practice, differing perhaps from that of most others, and which I have followed for several years with gratifying success, is as follows: Immediately after fruiting ceases I take up the plants with a spading fork, three or four to a forkful, disturbing the roots as little as possible, and set them one side; then thoroughly spade up the old row, clean out the weeds, fertilize, trench and then set the plants back, being careful to keep the blocks of earth intact; arrange the runners for rooting, and later on cut off only the weaker runners if in too great profusion. The first runners sent out by the old plant are larger and more vigorous than those produced later, thus making stronger plants. The importance of replanting at once after the plants have ceased fruiting will therefore readily be seen. A delay of three or four weeks, if not resulting in entire failure, would be likely to show a great reduction in the size and vigor of the new plants, and render them less capable of enduring the Winter freezing. By this system I have grown strawberries successfully year after year upon the same ground. In resetting probably not more than one-half or one-third of the old plants would be required to fill the worked-over rows, while the remainder could be used in enlarging the plot if desired. In fertilizing I have found fine ground bone and sulphate of potash, in the proportion of about four to one, very satisfactory, and estimate production at the rate of about 5,000 quarts per acre.



PLAN OF FARM WATER WORKS. 165.

My method of mulching and Winter protection also differs from that usually recommended. In August or September, with a spading fork, I take up sods about one foot square, thoroughly shaking out the earth. After lying reversed in the sun for a couple of months the grass roots become entirely dead. Along in November I trim the edges of each matted row with sods, allowing them to cover the ground close up to (not on) the plants. This prevents all damage from freezing and thawing. No other covering is required. Have sometimes used cornstalks, etc., as additional covering for some of the rows, but perceive no benefit from such use. No Summer mulching of hay, etc., to keep the berries clean is necessary, the sods forming a perfect protection. After fruiting is over, while working the rows, the sods are turned under, thus materially increasing the humus and fertility of the soil—no small gain. My experience in growing strawberries in hills has not been successful. I have discovered no increase in size, and a material decrease in production as compared with narrow matted rows. The reason is plain. The strawberry is a perennial. When confined to hills reliance is placed upon a single plant to form several crowns, which are expected to fruit the following season, all runners from the original plant being cut off as they appear. The plant being deprived of the natural power of reproduction from runners is compelled to form crowns. Reproduction from runners is natural; from crowns unnatural. A certain amount of the plant's vigor in sending out the runners has been wasted, and, of course, is not available for the crowns. Would it be risking too much to assert that a strong, well-rooted runner plant would produce more berries, equally large, than any single one of the forced crowns upon the original plant? As well expect a half-peck of potatoes planted in one hill to equal the product of a score of hills planted to single tubers.

Connecticut. H. H. BOARDMAN.

EVERYBODY'S GARDEN.

Experience With Cabbage and Club-Root.

As this disease is yearly becoming more prevalent and proportionately causing more and more damage to the cabbage crop, it may not be amiss to note some personal experiences. In February, 1898, I was called upon by a representative of a famous cabbage-growing district to suggest, if possible, some remedy for the club-root, which was forcing many of the growers to abandon the growing of the crop. In April following the locality was visited, and from a careful study of the situation, and inquiry into various places of the progress of the disease, it seemed reasonably certain that the disease, once started, was fostered and increasing to an alarming extent through a seriously acid state of the soil. There was no apparent lack of fertility, as stable manure was used in abundance, and fine crops of various kinds as strawberries, carrots, potatoes, corn, etc., were grown; but cabbage, cauliflower, wild mustard, in fact, everything subject to the disease, was alike attacked by it. Selecting a plot of ground which had been abandoned for cabbage growing (the last crop planted having been a total failure), I made tests with blue litmus paper, and found my suspicions as to acidity well founded on fact. Portions of the soil in which the test revealed a serious degree of acidity, were, after testing, treated with air-slaked lime, and placed in closely-covered tin boxes. After 48 hours they were again treated, and scarcely any traces of the acid were visible. At my suggestion, the cabbage was grown under exact usual methods, except the application of air-slaked lime at the rate of 2,000 pounds to the acre. On May 9 the ground received a heavy dressing of stable manure, and was plowed very shallow, barely sufficient to cover the manure.

Very few plants were grown in the infected district, most of them being obtained from outside localities known to be free from the disease. To make the test as thorough as possible, a strip through the center of the plot was limed after the plowing, and the seed was sown. This is by no means a safe practice or one under any circumstances to be recommended; but was done in this case to give as broad scope as possible to the test, as above stated. June 19 the ground was deeply plowed, and the lime at the above-mentioned rate was applied and thoroughly worked into the soil. The ground remained in this condition for about two weeks, or until sufficient rain fell to make the work of transplanting reasonably safe, after which the plants were set out. When the main portion of the plot had been set, the plants were all removed from the seed bed, which, after being deeply plowed, was planted, the same as the remainder of the plot. In transplanting a few diseased plants were found, which of course were discarded. Thorough cultivation was kept up, and the following report as to results was forwarded to me November 20: Whole number of plants set out, 2,200. Number found clubbed to greater or less extent, 121, which gave about .055 per cent affected. Of the number affected, some showed but very slight traces of the disease, while others were nearly or quite ruined. From the previous planting not one single cabbage was saved, and to reduce the disease from 100 to .055 in the one season's work was a very satisfactory showing.

Other troubles, as black rot, to a limited extent, Cabbage worms and drought were present; but as the test was made entirely as to the effect of lime upon club-root, no fungicides or insecticides were used. The results of the experiment may not prove altogether conclusive, as in the infected districts, the disease is more destructive some years than others, which may develop the fact that weather conditions may have somewhat to do with the matter. Again, under other soil conditions, some other agent than lime may prove effective. Under ordinary conditions, however, lime will prove a very efficient remedy, but when once developed great care should be exercised to prevent the spread of the disease. All affected roots should be boiled or burned and never fed to stock, and all tools used in the cultivation of the crop should be thoroughly cleaned before using in other ground. J. E. MORSE.

Michigan.

SMYRNA FIGS GROWING IN CALIFORNIA.

Curious Experiments With Insects.

For centuries the cured figs of western Turkey have been considered the best in the world. The Smyrna brand has long been and now is the most famous, and in reality has the most delicious flavor of any. To secure the varieties for our own country, learn the method of culture, to obtain the fruit and cure and otherwise treat it, so as to equal this foreign product, has long been a matter of earnest endeavor by the California fruit growers. The foremost experimenter in this matter was F. Roeding, and later George C. Roeding, of Fresno. The former sent W. C. West to Smyrna in 1885 to make personal investigation, and, if possible, procure cuttings of the variety from which the celebrated brand was made. This was accomplished at a cost of $3,000. The fruit was grown in the district of Aidin, 75 miles in the interior. But when trees were grown to bearing age they would not hold their fruit, but cast it when about the size of marbles. The cause was found to be lack of pollination. Something further had to be done. It should be understood that the flowers of figs are very small and within the fruits, and only reached through a small hole opposite the stem.

In studying the subject of fig pollination the Aidin or Smyrna variety was found to contain only female flowers. In the varieties that are commonly grown in California and elsewhere in the warmer parts of other States, they bear only mule flowers, or those which are totally incapable of being fertilized, while those of the Smyrna fig being perfect are easily susceptible to pollination. In a wild variety of the fig called Capri, which grows in Asia Minor, there are male, female and mule flowers, and besides, what is known as "gall" flowers, which are abnormal or partially developed female flowers, in which a very small insect breeds. The fruit, however, is small and not edible. This insect, popularly known as the Fig wasp, and scientifically as Blastophaga psenes, is the secret agent of fig pollination, and indispensable to the production of perfect fruit. There are other figs besides the Smyrna, that are large and well developed in flesh, but they lack perfect seeds and hence do not have the peculiar rich, nutty flavor of the Smyrna, which has perfect seeds, when the flowers are pollinated. Moreover, as has before been stated, this variety depends entirely upon the tiny Fig wasp for perfection of its fruit and also for that of the seeds. Fortunately, the Fig wasp finds in the gall flowers of the Capri fig a depository for its eggs, where they develop into perfect insects, and the females after impregnation while yet in the galls, emerge from them, wander about inside the fig, get covered with pollen from the male flowers, which are just then in bloom, and some of them crawl outside, carrying this covering of pollen. As they lose their wings in the act of getting out of the Capri fig they cannot fly to the edible fig trees, or they would pollenize their fruit without aid. But here comes in the hand of man, who, having learned all the foregoing facts, picks off the Capri figs when they are in just the right condition, strings them on strong threads and hangs them in the Smyrna fig trees. There the insects crawl out gradually and into the forming fruit and thus carry the pollen grains to the stigmas of the female flowers in their vain search for a new place to deposit their eggs. They die soon after. Those that remain in the wild or Capri figs deposit their eggs in the gall flowers, and thus perpetuate their own species.

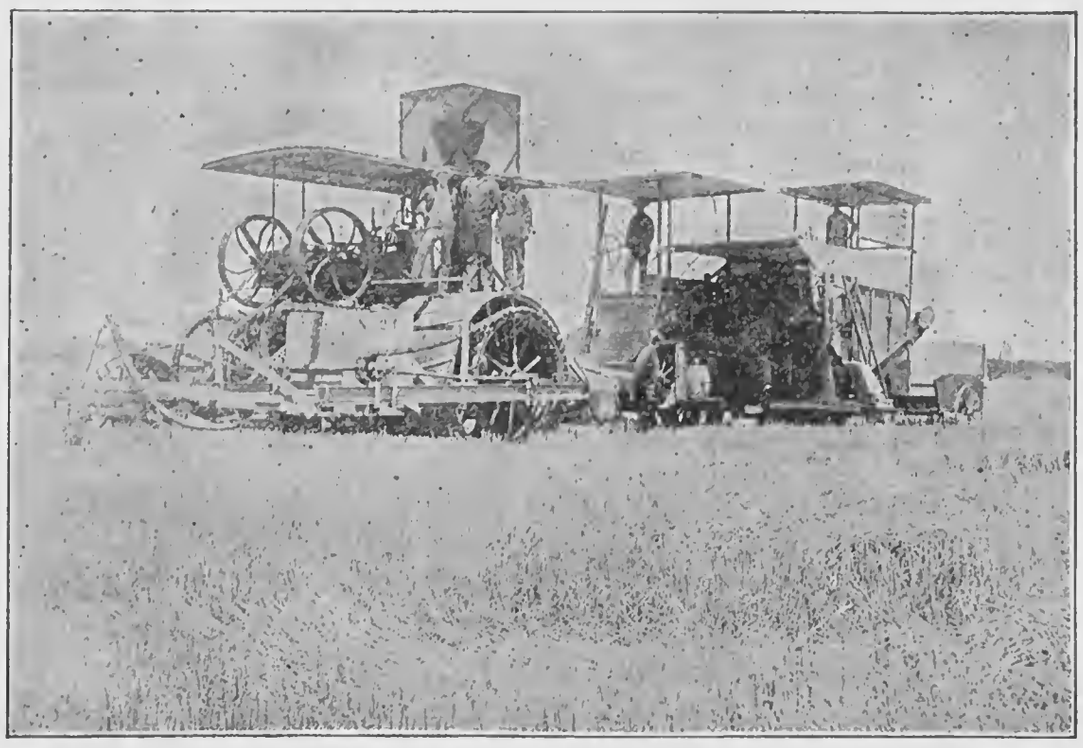
It was many years after fig growing had been begun in California before all of the above facts were known, and even then many believed them to be only idle theories. But persistent effort brought about the desired result, the production of perfect fruit on the Smyrna fig trees that had been grown from the imported cuttings. This, however, was not possible until Capri fig trees had been grown and a stock of the insects brought from Turkey. Cuttings of the Capri fig were first imported, that the insects would have a place in which to breed. Several lots were brought over, the largest of which was that imported by the United States Department of Agriculture in 1890, having been collected under my special directions by our consuls in Turkey and distributed by me throughout the entire fig-growing districts of the country. These grew readily and are now standing and their fruit in part inhabited by the Fig wasps, which have been successfully imported from the same source in Turkey, under the directions of Dr. L. O. Howard, entomologist of the Department of Agriculture.

Last Fall I had a package of cured figs from George C. Roeding, of Fresno, Cal., that are from his Smyrna orchard of 60 acres. Last year, for the first time, he was able to pollenize a sufficient quantity of the growing figs to make enough of the cured product for market. In all he has about two tons. The quality is equal to the best of that imported from Smyrna. It is sweet, aromatic and has the peculiar nutty flavor so much esteemed, and the texture of the skin is soft and pliant. We will soon no longer need to send abroad for choice figs. This large orchard will be brought into profitable bearing and others likewise. Many more will be planted, and the Turks will have to find a market elsewhere for their figs, just as they are having to do with their prunes. The size of the fresh Smyrna fig is not so large as that of many other kinds, averaging about 1¾ inch in diameter. The shape is flat, like that of a very wide decanter, with a slightly curved bottle neck about half an inch long. The color is clear, lemon yellow, with faint streaks of pale green on most specimens. Inside the color is brownish yellow. The flesh is soft yet meaty, with a central cavity of medium size. Those who like fresh figs would surely eat this variety with relish, for the flavor is very sweet and delicious. A life-size sectional drawing is seen at Fig. 164, made from a specimen grown by Mr. Roeding, of Fresno, Cal.

H. E. VAN DEMAN.

WHOLESALE WHEAT HARVESTING.

Many farmers in the Eastern States have witnessed the development of wheat harvesting. They started with the old sickle or grain cradle, and followed the mower and the crude reaper to the modern self-binding harvester. This machine is considered nearly perfect, yet the bundles must be handled again and again before the thrasher will turn out the clean grain. On the smaller eastern farms the self-binder will probably remain the standard for many years to come. In California and other western States, where thousands of acres may be cultivated as one field, larger and more powerful machines are possible. Fig. 166 shows an outfit quite common in parts of California. The picture is taken from Bulletin 24 of the United States Department of Agriculture (Division of Vegetable Physiology). The machine is a combined harvester and thrasher. It requires a strong traction engine or 28 to 40 horses to haul it at good speed. It performs the whole operation of thrashing and reaping. The straw is taken up in front in the machine, passes along and is thrown off at one side, while the cleaned grain is delivered into bags. In the dry climate of California this is possible—of course it could not be done in moist sections of the country. The bags are even left for weeks, where they fall from the machine, without harm. This is wholesale wheat farming, and if it were possible to prepare and fertilize the soil as well as the smaller eastern farms are cared for it is hard to see how eastern farmers could compete. Surely, the man who will not care for his 10 acres any better than the Californian cares for his 1,000 cannot hope to raise profitable grain.



STEAM HARVESTER-THRASHER USED IN CALIFORNIA. Fig. 166.

THAT MOTH CATCHER AGAIN.

We recently referred to the Haseltine moth catcher, and told how the manufacturer garbled a letter from Prof. Steadman. This seems to be a common trick. He did much the same thing with a letter from Prof. A. L. Quaintance, of the Georgia Experiment Station. Prof. Quaintance tried the trap on the moth of the so-called pickle worm, and finally sent the following letter to Mr. Haseltine:

> We tested your moth trap during the past Summer. We used it particularly to determine the possible value of trapping by lights of the so-called pickle-worm moth. With this insect we found that a great many were attracted to the light, and it would seem possible to endeavor to destroy these moths by some form of light trap. We had a good chance to observe the number of moths of the boll worm that were attracted to the light. One light was placed and kept burning adjacent to cornfields and cotton fields. Thousands of these moths could be observed in the afternoon and evening flying around here and there. Despite their unusual abundance, very few came to the trap, and I doubt whether this insect is attracted very much by light. The whole question of the value of any lamp, it seems to me, depends upon the species in question, as it is well known that certain moths will come to lamps when others will not. No wholesale claims, therefore, should be made for any light trap. I am glad to say that your lamp was found very effective in trapping moths of the pickle worm, and considered in connection with its cheapness, I think it would not be expecting too much of cucurbit growers to purchase it for use.

That seems plain and fair enough, but the trap man left out all reference to what the trap would *not* do, but put in the few lines about the pickle worm as though they referred to the Codling moth and other orchard insects. This may seem like a small thing, but the principle is a bad one. There can be no telling where the thing will end if men are permitted to garble letters in this way without being exposed.

THE LAW OF ANIMALS.

Horses Left Unguarded on the Highway.

The highway is for the reasonable use of all persons according to the ordinary practices and usages of life and business. One using the highway takes a certain amount of risk of accident, while those remaining upon their premises are entitled to a more absolute security. Farmers and gardeners are particularly interested in the rule of law relating to the practice of leaving horses unhitched or unguarded in the streets or highways. Many are called upon to pay damages or defend a law suit, growing out of despoliation of lawns or runaway horses. The prevailing rule appears to be that the leaving of horses unhitched and unguarded is not negligence per se, but according to the decisions it depends upon the disposition of the horse and many other circumstances, and the question of damages is to be determined by the jury from the facts of each case.

In Kansas it was recently held that a person is liable for an injury done by his runaway horse that had been left untied, though the driver is careful, and the horse an ordinarily gentle one. The court said that "the driver of a horse left unhitched ought to be near him and in a condition to control him by his voice and to reach him, if necessary, with his hand in an emergency." In California, Minnesota and other States it is held that the failure to comply with an ordinance making it unlawful to leave a horse unhitched, whereby the animals run away and do damage, is held to be negligence per se. Where a horse is high-spirited or addicted to running away, or the place is a crowded city street, or there has been negligence in the hitching or guarding, the owner will be liable. It is not material what frightens a horse, if he is not properly taken care of so as to prevent his running. The leaving of a horse unhitched or unattended need not be the immediate cause of the injury. An owner was held liable where the damage was occasioned by the act of a passerby in striking the horse. It is the duty of the owner of a horse to guard against such an accident, and his neglect involves him in liability for the consequences as well as the person who caused the frightening of the horse. A horse must be securely tied. The fact that a horse would not have run away if it had not been hit by stones thrown by boys does not relieve the owner from liability to an injured person, where the horse was tied with a flimsy and defective rope.

Where the driver of a carriage used to convey passengers for hire left the horses unhitched and unguarded while a passenger was inside, and they ran away, and the passenger was injured while trying to jump out, the driver and owner were held liable jointly or severally. A carriage at standstill upon the highway, the driver of the horses attached is liable to the statutory penalty if negligently or wilfully he is at such a distance that he cannot have the direction or government of the horses. When a gardener negligently left his horse and cart unattended and unhitched in the street, and the plaintiff, a child seven years old, got into the cart to play, and another child led the horse on, whereby the plaintiff was thrown out and hurt, the court said the owner was the real cause of the mischief, and therefore liable. Where a servant unlawfully left his master's horse unhitched, and the horse strolled away and collided with a ladder erected in the middle of the street upon which the plaintiff was working, the failure of the latter to have the ladder guarded did not relieve the owner of the horse from liability. It was the servant's negligence that contributed to the damage. It was recently said by the highest court of Georgia that "every horse whatever, no matter how gentle and amiable, must be properly attended or secured in the crowded business streets of a city, when there by the act of the owner and subject to control." R. D. F.

Farmers' Club.

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see whether it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

Compost of Fish.

W. F., Hornby Island, B. C.—How can I convert dogfish into manure to be drilled in with crops or spread broadcast and harrowed in? A neighbor advised me to get a barrel, put fish in with water, and add some muriatic acid; then dry with swamp muck or road scrapings or dust; that is, after the fish had been dissolved by the acid. What kind of acid should I use, and what amount to a 50-gallon barrel of dogfish?

ANS.—We hardly think it would pay to use acid on the fish. Where crops like corn or cabbage are planted in hills the fish can be dropped in like manure and covered. Some farmers near Long Island Sound are said to get good returns from fish used in this way. Fish can usually be rotted in a compost with lime, muck or manure. By putting the fish in layers with muck between and using lime freely a fair compost results.

A Potato Picker.

Reader (No Address).—I have invented a machine to pick up potatoes after being dug with a digger. It is simple and strong, and can be sold for from $50 to $75 with a fair profit to the maker and seller. It will take one man and boy who can handle a team to run it. It will handle the potatoes without bruising or skinning the tubers any more than when handled on an average by hand. Would there be sale enough to warrant anyone in putting money into a machine of that sort?

ANS.—We doubt it. The picker would cost too much for the average farmer. What is to prevent its picking up small stones with the potatoes? On stony farms this would be a great objection. Some of the larger growers in the West, on level ground, free from stones, could probably use such a machine, but we doubt whether it would have sale enough to pay.

Sterile Grapevine.

L. G., Independence, O.—We have a seedling grapevine which blossoms abundantly and in large clusters. The vine itself is strong and vigorous. The blossoms fall off, but the fruit does not set. It seems to blight. Can you give me any information in regard to its cause, or how to induce it to bear? The vine is nearly five years old.

ANS.—It is probable that the vine is of such character that its flowers are imperfect and will not produce fruit. In some cases the flowers are staminate, and in others they are pistillate. In the latter case they sometimes may be fertilized by the pollen of other varieties; but there are great variations in the potency of the pollen of one variety upon another, or they may not always bloom at the same time. The best way to treat this vine would probably be to graft it next Spring to some good variety.

Home-Grown Grass Seeds.

Several Readers.—Why can we not raise our own seeds of Timothy, Red-top, Orchard grass, etc., as we do seed of wheat, oats or corn? Is there any good reason for not doing it? Is there any book which tells how to do it?

ANS.—There is no reason why farmers should not raise their own grass seed as well as their own clover seed. The principal difficulty is the thrashing and cleaning of the seed. For home use this is, however, not such a serious matter, since seed is just as good when sown in the rough as when sown clean, although, of course, a great deal more must be used, and this increases the trouble of handling. There are usually very few weeds in the grass fields that are as tall as the grass, and that ripen at the same time. For instance, in Kentucky Blue-grass fields there are very few weeds when the field is well kept, and those that are present generally ripen their seeds later than the Blue-grass harvest. This seed could readily be stripped with a hand stripper, cured and dried, and run through a feed cutter to make it easier to handle. It can then be sown in the rough with quite as good results as when the fancy seed is used. Usually there is about 60 per cent of fancy seed in the rough. Orchard grass, Timothy and fescue might be run through a regular thrashing machine with the cylinders set close. The chaff could be blown out as much as convenient with a hand fanning-mill and the remainder used on the home farm. In the early days of the settlements in America clover seed was sown in the hull, there being no convenient means of hulling it. When clover seed became an article of commerce it was, of course, impossible to handle it in that way, but this method gave good satisfaction on the home place. I know of no pamphlet or book dealing with the commercial handling or preparation of grass seeds except one book in German, which is hardly accessible to American readers, and this applies more to German than to American conditions. This office has in preparation a paper on Kentucky Blue-grass seed, and we hope to follow this with other papers on the various grass seeds.

A. J. PIETERS,
In Charge of Seed Laboratory, Dep't of Agriculture.

Japan Millet for Pasture.

W. O. B., Fairfield, Conn.—Will the annual Japan millet do for pasture? We have pasture so far from home that it is impossible to grow fodder to cut green every day, yet we wish to sow something to increase the amount of feed. Is there anything better than millet?

ANS.—Millet is not a valuable crop for pasturage. It will not remain vigorous when constantly "cropped off" by cattle, as it naturally makes a thin bottom growth, with very little tendency to produce turf. If millet is wanted for cutting green and for feeding in the manger or feeding rack, it will make good fodder for use in the latter part of July and the early part of August. It requires about eight weeks from seeding to be in condition for feeding. Better crops for pasturage are rye or barley. The latter, when sown about July 20 at the rate of two bushels per acre, will produce good pasture feed from September 20 until the ground is badly frozen.

C. S. PHELPS.

The Resin-Lime Spraying Mixture.

W. T., Belle Plaine, Ia.—Tell us how to make the "resin-lime mixture." Isaw it in THE R. N.-Y. last year; I think it was in Hope Farm Notes.

ANS.—This is the formula given by the New York Experiment Station: Five pounds of pulverized resin, one pound of concentrated lye, one pint of fish oil, five gallons of water. The oil is used to soften or dissolve the resin. Boil the oil, resin and water in an iron kettle. When the resin is softened add the lye—first dissolving it in water. Stir this well and then add four gallons more of hot water. Boil all this until you have a clear, amber-colored liquid which unites with cold water. This makes a "liquid soap" which when put with the Paris-green and water will make it stick well to leaf or stem. It is hard stuff to spray—only a powerful pump will force it through the nozzle. When you add the potash and water you must let the kettle cool slightly. If this is not done the whole mass may boil over and the oil and resin will take fire.

Self-Cleaning Cattle Stables.

W. R., Wingham, Ont.—I intend to re-model my cattle stables, and would like to adopt some plan which would allow of the manure being removed at intervals of two weeks or more, instead of having to clean stables every day as at present. The self-cleaning stables, described in E. W. Stewart's book, "Feeding Animals," I think would meet the requirements of my case if they can be relied upon to do the work in common practice. As I have never had the opportunity of seeing a stable fitted with these grates I would like to read the experience of some practical farmers who have tested the self-cleaning stables.

ANS.—We have seen the iron grating over a trench behind the cows in operation, but do not think it is in common use. In some modern barns a steel rail is run behind and over the cows. On this runs a sheet-iron car or large scoop. The manure is thrown into it as it passes along and it is finally run out to the yard and dumped. In some bank barns there is a cement or plank gutter behind the cows. Every 50 feet or so there is a trap door through this gutter, under which hangs a large steel box. The manure is pushed along with a scraper and falls through the trap door into the box, which is unloaded by driving a dump cart under it and tipping it up. There are other plans for getting rid of manure, and we shall be glad to have our readers describe the devices they have found useful.

Sprays for Plum Blight and Red Spider.

A. B. W., Newlin, Pa.—1. I wish to use Bordeaux Mixture on my plum trees, also on grapevines, I see it recommended for rot in both cases. How much dry Bordeaux can I mix with a gallon of water, so it will keep off the rot, and at the same time not injure the foliage? 2. What shall I put on my rose bushes to kill the red spider, the leaf hopper and the slugs?

ANS.—1. The foliage of plums and most other stone fruits is quite sensitive to copper sulphate applications. To fight the rot successfully it is necessary thoroughly to spray before the buds open, using a mixture of four pounds copper sulphate and six pounds lime to 50 gallons water; again soon after the blooms have fallen and finally as the fruits begin to color. All applications after the leaves come out should be reduced to half strength or at the rate of two pounds copper sulphate and three of lime to 50 gallons of water. Dry Bordeaux and Fungiroid may be used at the rate of one pound to three gallons of water for first application and one to five or six gallons for the subsequent ones. 2. Cold water sprayed forcibly and repeatedly on under-side of the leaves is a sure cure for red spider, and will do much to dislodge leaf hoppers. Whale-oil soap, four to six ounces to the gallon of water, applied in the same manner, is more effectual. Dusting the bushes with dry quicklime is best for slugs, though dry road dust will often check their ravages.

THE IDAHO PEAR.—This is grown here in very limited quantities, and no new trees are planted out. The fruit grows very large, and is of little value. It ought to be picked before it is ripe, and laid away in a cool place, and then it will mellow somewhat; otherwise it is too gritty. When it does ripen, it ripens all over and at once, lasts just one day in good condition, and the next it is all mushy. As we are about 1,000 miles from the Rocky Mountain region I am not advised, how it does there; I can only speak for Oregon, Washington and Idaho. Personally I would not give it room in my grounds. It is worse than the Ben Davis apple. HENRY E. DOSCH.

The Cornell Reading Course.

Edited by John Craig, Professor of University Extension, and Editor Farmers' Reading Course, Cornell University, Ithaca, N. Y.

PEACH LEAF-CURL.

Rain is a fine thing but it has its limitations. The cool, moist weather which has characterized the Spring has been most favorable for the development of Peach leaf-curl. By the time this note comes before the eye of the members of our Reading Course the damage will be done, and while it is too late to talk of remedies, so far as the crop of this year is concerned, yet it will be profitable to them in the light of the future. Every now and then when the peach buds have escaped frost, fruit has set and a crop is fairly well assured, Peach curl comes along as it promises to do this year, and wipes out the prospective harvest.

WHAT THE PEST IS.—This is a fungus disease, and has long been known to orchardists and botanists. Most of you know how it looks. The first indications of its presence are a roughened surface of the leaf with a reddish coloration. With the development of the leaf comes a curling and swelling. Sometimes only a part of the leaf is involved, and again the whole surface. By the time the leaf is full grown the diseased patches are usually a reddish green, occasionally a bleached yellow. As the disease progresses the leaf-stalk is affected also, becomes swollen and loses its deep green color. Later on the surface of the leaves takes on a grayish, powdery appearance. This expression is due to the production of myriads of spores which reproduce and disseminate the disease. The next stage is the withering and dropping of the leaves, which may occur between the middle and end of June. The fall of the leaves does not usually mean the death of the tree, but it does mean the loss of the crop and the serious lowering of the vitality of the tree. It also gives the tree a severe shock and prevents the normal development of its fruit buds; therefore, affects next year's crop.

HOW THE FUNGUS LIVES.—In Bulletin No. 164 of Cornell University, Dr. Duggar says: "The fruit of the fungus (meaning the spores which reproduce the disease) is produced on the surface of the leaf, but the true vegetative state of the fungus is within the tissues of the leaf and the young shoots. The threads, or filaments, which make up this vegetative state, pass in between the cells of the leaf, and it is the irritation due to the presence of these fungous filaments (the mycelium) which causes the leaf to become distorted in form. Passing into the young shoot, the fungus is in a condition to pass the Winter in situ, provided the twig lives, without having to trust to the fortune of winds and rains, as is the case with the spore." The spores live over Winter and affect the buds which open the next season. This then briefly is the way in which the disease lives and is carried over from year to year. Certain climatic conditions greatly influence its development, as we have observed.

REMEDIES.—Fortunately experiments carried on at Cornell and elsewhere enable us to speak quite positively on this side of the question. Experiments in 1898 proved very conclusively that spraying early in the season was a preventive. The following year additional experiments were carried on which demonstrated beyond question that the disease might be thoroughly held in check by careful spraying, provided it was done early enough. Here are the recommendations of Dr. Duggar: "Spray with Bordeaux Mixture (ordinary strength) about the first of April when the buds are beginning to swell. Spray again when the petals have fallen, using two pounds each of copper sulphate and lime to 50 gallons of water." This second spraying may be omitted if the weather is dry and warm, but should it be cool and moist it would be altogether desirable to make the application. Peach foliage is sensitive to the use of copper-salt mixtures, but if used as directed above there will be no danger and the curl will, in a large measure, be prevented. The time element is important. A grower told me last week that he expected Peach curl and was going to spray. I told him that so far as immediate results were concerned he could save himself the trouble. He would undoubtedly kill some of the spores which might spread to other trees, but he would not help the trees very much this year except in the way of preventing a recurrence of the disease on the foliage developed later.

Peach Borers.

P. G. S., Morton, Pa.—I have a small orchard of peach trees on a farm I have just rented. The borers have pretty well killed the trees out—about one-third of the branches are in blossom, the remainder appear to be dead. What shall I do?

ANS.—The thing to do with these trees is to cut them down or grub them out by the roots. They will probably pay the renter and proprietor more in fuel than in fruit. When two-thirds of the branches of an orchard tree are dead it is almost certain that the days of usefulness of that tree are numbered.

H. E. VAN DEMAN.

The Snake River Valley.

F. V., Piqua, O.—Will you give me some information in regard to the Snake River Valley, Idaho? Is that country well settled with farmers? Is there a good farming country around Boise, Idaho? How is the farming country near Market Lake and Blackfoot? Do they grow much fruit? Is it a large prairie country? Do the farmers have wind-breaks; that is, maples, box elders and cottonwood trees? From what part of the United States do they get their fruit trees? By what class of people is that country settled? I am thinking of going to that country to live.

ANS.—Having recently been over a large part of the Snake River Valley, which is mostly in Idaho, I can say from careful observation that there is plenty of good land there. It is decidedly a sage-brush country, and this is a sure indication of a very light rainfall. Irrigation is essential; and wherever water is abundant, as is the case about Boise, Nampa, Payette, Weiser and many other places, there is excellent opportunity to grow almost any crops suitable to the temperate zone. Corn is not grown there much, but all the small grains, grasses, common orchard fruits, berries, vegetables, etc., do finely. They grow windbreaks of many kinds of forest trees, especially the Lombardy poplar, box elder and Yellow locust. There is good fir, pine and other timber in the mountains, but none in the valleys, except a little cottonwood along the streams. The settlers are mostly from the Central States, although some are from the East and a few from Scandinavia, England and Germany. It is a nice place to live and one who contemplates going there need not think of starving, or of not enjoying good society and church and school privileges.

H. E. VAN DEMAN.

Early Clover Seeding.

One of our readers wishes to know whether anyone has ever practiced sowing clover seed as early as December or January, letting it freeze and thaw down into the ground, so as to get a better chance to grow when frost is past.

ANS.—The Michigan Agricultural College sowed clover seed every month in the year, and succeeded in getting more or less of a stand from the sowing each time. The value of such a plan as that proposed in the inquiry would depend almost entirely on the character of the climate. If the person lived in the Northern States, and a thaw occurred in the Winter, and the ground were left in the condition named, and if the character of the Winters in that locality was such that pretty steady and hard weather should follow the thaw, then the plan of sowing seed thus would succeed well. But if, on the other hand, it was probable that there would be much of that weather which produces a honeycombed condition of the ground between the date of sowing the seed and the opening of Spring, or the period of consecutive growth, then there would be more or less danger that the clover would sprout and receive injury from hard freezing after it so sprouted. The danger of this is not very great, but in some climates it would be present more or less; hence, in these it would be prudent to wait until a later period of such freezing and thawing alternately before sowing the seed. In the Northwestern States it happens once in a while, though not frequently, that the Spring clover plants are injured by a hard frost after they have begun to grow; hence, in any climates similar to that, it would be unwise to sow seed during a warm spell in the month of January should such weather occur. [Prof.] THOS. SHAW.

Questions About Pears.

D. E. F., Toledo, O.—In 1882 I planted 10 acres to standard pear trees. The trees have been properly trimmed and the ground well worked throughout the orchard. On the west side I planted five rows of Anjou pear trees, then four rows of Sheldon trees, and next to them Flemish Beauty, Bartlett and Angoulême, all of which bear heavy crops of fruit, excepting the Anjou trees. The latter blossom very full every Spring but bear little, the blossoms all dropping off without setting much fruit. They are planted 20 feet apart each way in the rows, and all thrifty trees. What is the trouble with my Anjous? Does the standard Anjou under any condition ever bear a heavy crop?

ANS.—There is so much complaint of the scant bearing of the Anjou pear, especially on pear roots, that the case mentioned by D. E. F. cannot be considered very unusual. In some cases it bears well and I have in mind some old standard trees that bear regularly and heavy. As a dwarf the Anjou generally bears sufficiently, but the fruit is so large and has such short stems that very much of it is blown off by ordinary winds, and storms are apt about to strip the trees. It is a good late Fall pear, but quite hard to get in paying quantities.

Grafting Dwarf Apples; Various Questions.

J. R. C., Means, O.—1. Can you graft standard on dwarf apples and with what effect? 2. Describe Arkansas Black, Mann and Bismarck apples. Also describe the Grand Duke, Lincoln and Golden Drop plums. Are the above suitable to plant in northeastern Ohio?

ANS.—1. Any variety of apple can be successfully grafted on any other, no matter whether the trees are on standard or dwarf stocks. The stock does not materially change the character of the graft. It will cause it to grow more thriftily if the stock is thrifty, than if it is not so, and the reverse is also true. A dwarf apple stock, such as the Paradise or Doucain, will not allow a scion or bud put upon it to grow into a standard tree, and that is all the effect it has upon it. 2. The Arkansas Black apple is a seedling of Winesap that is so dark red as to be almost black. It is a little larger than its parent but not so good in quality and has the fault of dropping very badly from the tree early in the Fall. It has rarely proved to be worthy of cultivation. Mann is a very late keeper, bears well and is of fair quality when fully ripe, but the color is a dull bronzy green almost as long as it lasts, and this renders it undesirable in market. For home use it is quite suitable. Bismarck is a very newly-introduced apple, and, so far as I have knowledge of it, is more prominent for its early bearing than for anything else. It is of fair size, red striped and attractive, but I would take it only on trial and in a small way. Grand Duke plum is one of the standard market kinds. It is dark purple, large, fair in quality and late in ripening. Lincoln is a fairly good plum in all respects, being medium in size, purple, and of good quality, but of no unusual superiority. Golden Drop is one of the best of the yellow plums. It is large, of good quality and a fairly good bearer. All the varieties mentioned will do fairly well in northeastern Ohio.

BULL-STRONG!

....PIG-TIGHT....

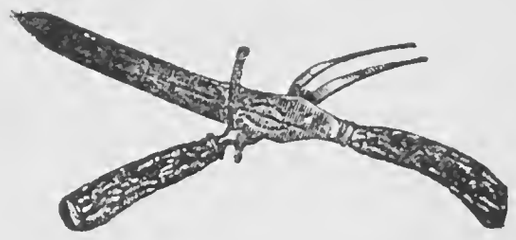
An Illinois farmer said that after harvest he had fully 200 bushels of loose oats on the ground that he could not secure any benefit from, because the fence around the field would not turn hogs. Figure the loss for yourself. He also said, all this would have been saved if he had used the Kitselman Woven Wire **Coiled Spring Fence**, and the value would have gone a long ways towards paying cost of the fence. With the **Duplex Machine** any farmer can make it himself at the actual cost of the wire. Catalogue free for the asking. KITSELMAN BROS., Box D92. Munole, Ind.

35 years of square dealing has brought to Jones of Binghamton, N. Y., the confidence of the world, and every mail brings cash with the order by which the purchaser saves from 5 to 50 dollars, according to the size scale he buys. Jones he pays the freight.

Why Not Preserve Wheat and Rye Straw Straight Bound in Bundles? Please your customers by saving barn room and saving labor in handling straw. Our Combined Straw-Preserving and Spike-Tooth Thrasher we guarantee to thrash Wheat or Rye perfectly clean and not bruise or break the straw, and bind the straw again in perfect bundles. The same machine can be changed in 15 minutes to a Spike-Tooth Oat, Wheat, Buckwheat, Barley and Corn Thrasher with Stacker attached. Will thrash and clean more grain with less power than any machine built. Send for catalogue B. GRANT-FERRIS COMPANY, Troy, N. Y.

A Carving Set.

Every family needs a carving set three times a day. This set consists of a Sheffield carver with eight-inch handmade



steel blade, buckhorn handle, fork and steel. Price, $1.90; or we will send it for a club of two new subscriptions at $1 each and $1.25 extra money, or free for a club of six at $1 each.

Ruralisms

NOTES FROM THE RURAL GROUNDS.

PLUM BLOSSOMS.—The illustration, Fig. 163, well represents the profusion of bloom on an established Burbank plum tree. The photograph was taken in the poultry yard of Dr. D. L. Long, Reading, Pa. The trees have only been set three or four years, and bore a good crop last season. No plum of our acquaintance so covers itself with wreaths of bloom as this excellent variety, although most of the Japan sorts produce their flowers in dense clusters. Frequently several fruits develop in a cluster, rendering it necessary to thin out in order to get full-sized specimens. The American and European plums do not usually bloom so densely, and the resulting fruits are better distributed along the branches. The Burbank plum is being largely planted by amateurs as well as fruit growers, and is giving general satisfaction on account of its productiveness and reliability. The plums are of good size and fair quality, but very subject to rot unless well thinned. The spreading habit renders it very suitable for poultry yards, where it thrives exceedingly well. The blossoms of the plum, cherry and some other stone fruits are very ornamental, and are made popular objects of admiration and reverence in Japan. Public festivals are held during the blooming season, that all may enjoy the beautiful effects. While fruit blossoms are not so highly appreciated with us the advent of the flowering period is looked to with the greatest interest by all horticulturists. It is possible to have a long succession of highly ornamental blooms by a judicious selection of varieties. The cool and moist weather has prolonged the present season, which has averaged at least 10 days late for the various sorts. On the Rural Grounds a Harris apricot opened its petals first, quickly followed by Prunus Simoni, and other apricots. Burbank, Wickson and Red June plums came next, merging into other Japan varieties. The American and European plums began to open just as the Japans faded. Peaches and most of the cherries bloomed at the same time. The Rocky Mountain, or Sand cherry, Prunus Besseyi, and the native Beach plum closed the season. They have been veritable clouds of bloom for several days, coming in with the apple and late pear blossoms. The Rocky Mountain cherry has the most symmetrical arrangement of its blooms around the slender branches of any variety we have grown, each twig becoming a perfect cylinder of blossoms. Were it not for its great susceptibility to twig blight it would be a meritorious shrub for ornamental planting. Several beautiful varieties of flowering cherries and plums are offered by good nurseries. The double-flowering plum, Prunus triloba, has pink, very double flowers closely set on the slender branches. The white and red double-flowering "almonds," so often seen in old dooryards, are really plums, varieties of P. Japonica, but the finest trees of this class are the weeping Japan cherries in several varieties. They always arrest attention when in bloom on account of their graceful form and billows of delicate flowers. The botanical name is Cerasus Japonica pendula.

POTATOES UNDER GLASS.—An English gardening journal speaks of an experiment in growing potatoes in a greenhouse. The tubers, of a favorite British variety, were planted in 12-inch pots during midwinter, and only two shoots finally allowed to a pot, 300 of which were placed together in a suitable structure. A mild heat, not often exceeding 60 degrees, was maintained. At the end of April the tops had made a luxuriant growth and the prospect of a good crop of new potatoes was very evident. Whether the price these hothouse potatoes should bring will compensate the grower is another question. Volunteer potato plants often come up in greenhouse benches, the tubers having been included by chance in the potting soil. If not disturbed they make a strong and rapid growth. The writer can testify to the excellent quality of the resulting potatoes, but has no knowledge of this useful esculent being purposely grown under protected conditions for use or profit in this country, though one would think glass-grown potatoes would be fully as desirable as beans and corn grown in the same manner.

BI-SEXUAL STRAWBERRIES INCREASING.—A review of the sexual characteristics of the numerous varieties of strawberries introduced to cultivation during the last 30 years shows that, contrary to general opinion, the proportion of staminate or perfect-flowering varieties is increasing. More than half of the new kinds have blooms of this character, while the great proportion of introductions during the early period in the improvement of native strawberries was exactly the reverse. The older cultivators preferred the pistillate varieties, as they secured better fruits when pollenization was effected by nearby perfect-blooming plants. The theory was that less energy was expended in producing perishable parts in the imperfect or pistillate blooms, and consequently a greater development of the berry pulp might follow. The practical difficulty in securing effective pollenization when large areas of pistillate sorts are planted has been sufficient to create a demand for good perfect varieties, and they have now reached a degree of development closely approaching the incomplete bloomers. While the proportion of staminate varieties is now greater, taking all the late introductions together, we find pistillate flowers greatly predominating among the new strawberries sent to THE R. N.-Y. for trial. We assume the reason to be the number of seedlings submitted by amateurs, who are more concerned with tne size and table quality of their berries than the general hustling qualities of the plants.

W. V. F.

Wide and Narrow Orchard Rows.

In response to F. W. P., on page 371, who wants to know if the plan has been tried which he suggests, for planting apple trees in rows that are wide apart east and west, but close north and south, I may say that it has been tried in my own orchards, and some others that I know for more than 25 years past. The plan works very well. There are several ways of applying the principle, such as the hexagonal, alternate and plain square systems. By either of these it is best to fill in with temporary trees of such varieties as will bear early and be ready to be removed when they interfere too much with those next to them. The distance I planted in Kansas was 33x16½ feet, that of Wellhouse is 32x16 feet, and that of Parker Earle is 32x20 feet. In the Eastern States, where apple trees grow larger and are more tardy in bearing than in the West the distance should be increased to 40x 18 or 50x20 feet. H. E. VAN DEMAN.

In answer to F. W. P., in THE R. N.-Y. of May 25, for the past 10 years I have planted all of my pear orchards (about 30 acres) on the plan he suggests; that is, 16x28 feet, the wide rows north and south. I think the advantages are better opportunity to cultivate crops planted in the orchard while young; when of bearing age a freer passage of air to help pollination when in bloom, and better passage through the orchard when gathering and hauling the fruit. I have known peach orchards planted on this plan which were satisfactory. This mode is better adapted to such fruits as the pear, peach and plum, that are usually planted at less distance than the apple, and soon cover the ground, obstructing free passage of air, cultivation and gathering the fruit. The apple that is usually planted much farther apart, 36 or 40 feet each way, has plenty of room for several years; still I think the plan would be satisfactory, as the same number of trees could be planted on the same ground and have more advantages of air, light, etc. When trees are full grown, if anyone will observe a single row of fruit trees, it will be seen that they do better than the dense shaded orchard.

CHAS. BLACK.

New Jersey.

Rabbits and Fruit Trees.

A friend in Missouri read the call for a device that will prevent rabbits from gnawing fruit trees. He sends a circular describing what is known as Davis's wire protector. The little picture (Fig 167) shows how it operates. The directions for putting it on the tree are as

WIRE TREE PROTECTOR. FIG. 167.

follows: Begin with the lower end of the protector and turn the coils two or three times around the tree (to the right or left according as the protector is coiled), after which the anchor is forced into the ground and the protector taken hold of at the top and turned in the reverse way around the tree until the coils are wound entirely around the same.

York Imperial Apple

Judge Wellhouse, "the apple king," says that while he has 200 acres of York Imperial apples, and they are very satisfactory, yet he would not discard the Ben Davis for them. They are handsomer, are of better flavor than the Ben Davis, and we find that under ordinary conditions, in reach of ordinary people, they keep crisp, hard, sound and juicy long after the Ben Davis had become mellow and practically worthless. Some of our orchardists are enthusiastic over it, and they think it the best apple they have. President Wellhouse says that the trees suffered more than Ben Davis during the extremely low temperature of February, 1899, although they have at the present time recuperated. We find that they come out of cold storage "scalded"; that is, they turn brown soon after coming out of cold store. I think this evidence that they will not stand or do not require as low a temperature as other varieties. Three years ago I put 87 varieties of apples in cold storage; they were in paper sacks, many kinds in the same barrel, so that the conditions must have been the same. The Dominie was the worst looking of all; it was as brown as a walnut all over, and on cutting in half I found that this brown color extended about one-fourth of an inch in depth all around the apple. Within this ring the apple was sound and of good flavor. Some other varieties, the names of which I have forgotten, were brown or scalded all over, but only skin deep, others again were scalded in spots. This proves that we must study each apple separately to determine the best temperature at which to keep it the most perfectly. I do indeed recommend planting the York Imperial, but I do not advise anyone to put his eggs all in one basket. Ben Davis, Missouri Pippin, Winesap, Jonathan, York Imperial, Gano and Ralls Genet make a sure-enough list in Kansas.

Hope Farm Notes

MISFIT WEATHER.—It still rains! We had two good days last week and one other that seemed to be trying to be good, but the force of habit was too strong, and it fell—that is, the rain did. We were obliged to start the fires in the house, the weather was so cold and dismal. Well, we can't fit the weather to suit—we shall have to fit the crops to suit the weather. When I was a young man trying to get through college my purse was as empty of cash as May is empty of sunshine. I did not have one full new suit of clothes all through my course. I became the victim or the heir of a couple of men in a distant city who wore their clothes until knees and elbows made a deep and permanent impression, and then gave them to my mother, who sent them to me. I never saw these gentlemen, but the one who sent me trousers was a man of girth and substance. I could give more dignity to his garments now, but in those days they set off my figure about as this wet May fits my farm plans. I used to pin up the slack at the waist and trim off the ends with a pair of shears. Happily the other man had a liking for coats with very long tails or skirts, which mercifully left much of my attempt at tailoring to the imagination. I didn't go to see the girls often in those days, but I learned some habits of taking things as they come which I wouldn't sell for King Edward's wardrobe. Why no, I am not ashamed of the fact I wore this cast-off clothing. I cast off the habit when I could afford to, and not a day before. Far better an old coat than a new debt. Far better to wait and work with faith that the hard condition will wear off at last and give a better fit.

FARM IS BEST.—I thought of all this as the cold rain bagged out and hung about our farm plans as those old clothes used to envelop my limbs. We must make our crops fit a little better, and hang on until we grow bigger. You can't expect a farmer to spend much time over poetry, but some lines by Edwin Markham have been running in my mind. He went down into Wall Street during the recent panic and saw the crazy rush and struggle of the stock gamblers. Here is part of it:

Is this a whirl of madmen ravening
And blowing bubbles in their merriment?
Is Babel come again with shrieking crew
To eat the dust and drink the roaring wind?
And all for what? A handful of bright sand
To buy a shroud with and a length of earth?

Oh, saner are the hearts on stiller ways!
Thrice happier they who, far from these wild hours,
Grow softly as the apples on a bough.
Wiser the plowman with his scudding blade,
Turning a straight, fresh furrow down a field—
Wiser the herdman whistling to his heart,
In the long shadows at the break of day—
Wiser the fisherman with quiet hand
Slanting his sail against the evening wind.

I have heard people who ought to know say that Markham is not a poet, but if what he says here is not true there is no truth left. Give me a farm paid for and stocked, with family and friends about me, and you may take Wall Street and all it represents. There are not millions enough in the Stock Exchange to buy the fun I can have sitting on my old stone wall eating a piece of bread and cheese that I have honestly earned. So rain on! As the children say: "It is good for grass and grain and Grandmother"—and we can't stop it.

RAIN NOTES.—Mind you now, I am not finding fault in relating some of our mishaps; I'm telling what happened. We thought the rain was surely over, and put all hands at work hauling manure for the late potatoes. The field is on the lower farm, naturally wet and sloping to a little brook. We plastered that field thick with fine, well-rotted manure. Nearly all of our Winter's supply went on that small field. Before 20 furrows could be plowed down came the rain again for three days. The nitrates were leached out of that manure in quick order. By this time they may be feeding the fishes in the Atlantic Ocean. You give a Jersey rain full swing and it will undo the work of a cement floor in short order. . . . Spraying is a failure with us this year. Just exactly at the right time a cold rain set in, and lasted three days, with showers following. Under such conditions spraying does little good. I sometimes wonder what the spraying "authorities" would do with their theories were they put on a farm in a season like this, with no salary except what the crops pay them. At the time for spraying the corn ground needs plowing, the first potatoes need cultivating and a dozen other jobs are pressing. It is simply a question of which to let go. . . I expected that the long wet season would ruin the cherry crop, but it has started well with a full "setting."

SOILING STOCK.—We have begun in a small way to cut green feed for the stock. The rye came first. As soon as it was large enough Hugh began to cut a small load every night. We fed it to cows, horses and pigs. The brood sows made good use of it, and it furnished a fair share of their food. Cows do not eat it readily after it gets hard, though Julia, our black cow, cleans it up better than the others. There was no trouble about making the milk taste when we fed the rye just after milking. Our Crimson clover is in the rye this year. This proves to be a mistake, for when the clover is at its best the rye is too hard to feed. The stock pick out the clover and leave the rye. I would cut and cure the whole crop if it were possible to dry it, but the rain prevents that until the rye is too hard to make hay. Thus we shall lose nearly all the feeding value of the clover. Another year I shall sow clover by itself and use wheat in place of part of the rye. We are seeding rape and turnips to feed the pigs during June and July, and corn fodder and sorghum for the cows. This soiling has its drawbacks unless you keep stock enough to make it a business and can put men at it for a fair share of the time. It is a sort of nuisance, after a hard day's work in the field, to take a scythe and cut fodder for a few head of stock. We have a small orchard of young trees across the lane from our pasture. It is now in rye and clover. When these are cut we shall drill fodder corn to throw over the fence to the stock.

LIVE STOCK NOTES.—The two young grade sows gave us 18 pigs between them. Both litters are strong and healthy. Every pig is white as snow, though the sows are grade Berkshires—well marked and nearly solid black! While these litters are late I think the pigs can be sold to good advantage. If not we shall have wastes enough to keep them cheaply. . . . We made our first sale of purebred stock when little Billy Berkshire left the farm. He is a good one—all but his tail, which fell off to a stub. The three little Berkshire sows are not for sale. They are good enough to help their mother give tone to the Hope Farm Berkshires. Billy weighed 31½ pounds at six weeks old. . . . Our "kicker" Julia has subsided. Charlie rigged up a device for crowding her into a corner where there was nothing to kick about. I always believed in prohibition. She gives her 12 quarts and more per day, but still looks out of the corner of her eye when she sees a milk pail. One thing about Julia is that she never "kicks" about her food. Straw, stalks, rye—anything that she can grind with her teeth will make a grist for milk. She would make milk out of what the other cows would "kick" about if given them for bedding.

The Hired Man Again.

FARM HOMES.—The labor and tenant problem touches all. I quite agree with the tenant plan as against the plan of boarding hired help. It is quite enough for hired help to know so much of one's private business without having them familiar with family matters also. It is also pleasanter for them to be rid of the "boss" part of the time. A. W.

Connecticut.

FARM PROFITS.—I see that the "hired man question" still takes space. I have thought sometimes that as I was but a worker and not a scientific man or something else but a workingman, my opinions did not amount to much; but I see that others think about as I do. Yes, I could make $1,000 profit on 100 acres of tillable land in any part of the United States if I had the means to work it properly. Of course, it could not be done in the first year, ad possibly not in the second, for it would take a man one year to learn his farm and perhaps another to find out what the market demanded and where his markets are. F. H.

Plymouth Co., Mass.

OVER-WORKED.—The man who thinks to get two or three times what he pays for out of a hired man or boy might with propriety consider himself a back number. In 1846 I worked for such a one, a big strong man who in the long Summer days drove me from daylight till dark, and got as much out of me by his side as he did himself, and he rested nearly every day from noon till four in the afternoon, while I was at work. He gave me about $9 a month and board, and used up all the day, from up in the morning till bedtime. This was before the war; farm wages for men were $12 or $13 and board; wages now are double what they were then, and board more than double. Reasoning people wonder how any man, even the poorest, can work at the wages Michigan Farmer says he pays and attempt to be satisfied with it.

Connecticut. H.

AT FIRST TABLE.—There is a great difference in hired men, also in the man who hires. I have paid good hands $20 a month and board, and was well pleased to get good men at that. They should have a good house to live in if married. I have worked for $10 a month when I was 20 and 21 years old; could not find my equal then on the farm. I was out in the southwestern part of Monroe Co., N. Y., when 22, and a well-to-do-farmer built a good large house and moved in, letting his hired man live in the old house. The next Summer he said he was going to build a new house as good as his own for his hired man and keep him as long as he was able to work, or as long as they both lived. If my memory serves me right it was ex-Gov. Bradford, of Connecticut, who, when asked by some city friends if he thought it right to eat with hired help, said: "My wife and I have been talking this matter up, and we have come to the conclusion that those who do the work should eat at the first table." Is not that right? Good farm hands first, or as good as there are.

BINDER TWINE

It affords us great pleasure to quote prices for our famous and well-known grades of binder twine as follows:

Pure White Sisal, 8c per lb. Standard, 8c per lb. Manila, 9¾c per lb.

These prices are for any quantity not less than a 50-pound bale, free on board cars Chicago, and are not subject to discount. TERMS:—Cash to accompany order.

The above twines are our unexcelled "SMYTH" BRAND, pronounced by all who have heretofore used them to be the best in the world. They are prepared with special care from first quality selected hemp, every ball being separately tested for evenness and tensile strength and insect prepared before being allowed to pass examination, hence it is absolutely perfect, is reputed the very best binder twine in the market and we believe it to be worth 2c per pound more than any other binder twine in the market.

WE GUARANTEE our customers against any change in our price and if we go lower, you will be refunded the difference in price. We treat all our customers alike and the early buyer is afforded as much protection as the late one.

SAMPLES FREE. We guarantee our twine, every pound of it, and we will refund your money instantly and without a question if it falls to come up to our representation either in quality or count, but if you prefer to see samples before ordering, then write to us and we will send samples by return mail so that you can see and test it.

"A SQUARE DEAL."

We believe that every advertisement in this paper is backed by a responsible person. But to make doubly sure we will make good any loss to paid subscribers sustained by trusting any deliberate swindler advertising in our columns, and any such swindler will be publicly exposed. W protect subscribers against rogues, but we do not guarantee to adjust trifling differences between subscribers and honest, responsible advertisers. Neither will we be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent us within one month of the time of the transaction, and you must have mentioned THE RURAL NEW-YORKER when writing the advertiser.

Name and address of sender, and what the remittance is for, should appear in every letter.
Remittances may be made in money order, express order, personal check or bank draft.
THE RURAL NEW-YORKER,
409 Pearl Street, New York.

SATURDAY, JUNE 8, 1901

THE oleo people receive little hope from the courts. Three oleo rogues in Philadelphia were convicted of selling their stuff illegally. They appealed to two higher courts, and were beaten. They then went to the United States Supreme Court, asking to have the decision against them reviewed. This has been denied, and now there is nothing for them to do but to face the music, which in this case might appropriately be "The Rogue's March."

*

Two sets of tendencies or forces work in the development of any animal. One is the tendency to follow after the parents or their ancestors—the other the inclination to vary or "sport." The latter is always strong. When the parents differ widely in type and the ancestors have not been well or uniformly bred it is easily seen that the chances of producing a useful animal are poor. It is a clear case of gambling with all the best cards in your opponent's hands.

*

A MAN who sent $1 to a concern for a "reliable tip" on the stock market, got a reply that stocks would soon go either up or down, they did not know which. Whatever may be said about their method of inducing the man to send his dollar, the reply was an honest one. "Tips" are usually good things to steer clear of, for most people who know how to make money quickly and easily take advantage of their own information rather than go around peddling it at a discount. Money is handy stuff to have, but a man may become fearfully one-sided both mentally and morally by making money-getting his sole aim. It would seem to be foolish for one to narrow and cripple himself in this way.

*

REPORTS from the Central West are that wheat is quite good in quality but that the acreage is light. Many farmers reasoned last Fall that they had had a total loss, and that wheat had not paid for 10 years. When they got a fair crop the price went down to 60 cents. For the first time in the lives of many they had to buy their own seed. About half an acreage was the result. Machine men say that binders were not worn out the last two years, and that there is not the usual demand for them. Mowers are selling well, and corn planters and cultivators quite well. Corn has been the paying crop for several years past. The export demand holds prices up, and many think that it will soon be equal in price with wheat. The large acreage of corn for two years past will make a big wheat sowing this Fall in order to rest land corned twice. Farmers are prosperous, independent and happy. Their homes are more beautiful and convenient than in the past. A good indication of rural prosperity is the fact that many new telephone lines are stretching out to the farmhouses.

*

THE pioneer of a century ago cut a hole in the forest, built a log house and began the struggle for food. His clearing was small at first. The trees about it were high, and shadows brooded in it. It was a dismal place on stormy or gloomy days. Life seemed to be narrowed into a little square. In many cases the woman sickened and pined away. The man lost heart and went back where some one else had made a larger place for the sunshine. Others had stouter hearts. They kept at work with their axes in spite of shadow and doubt and loneliness. Tree by tree the forest fell away and the plow followed. Slowly the farm spread, and the sun came in until, finally, almost before the farmer realized what he was doing he looked out over broad acres and found that he had saved his farm. How proud such a farmer must have been to realize that he had fought the wilderness successfully and cleared the land! Yet, has he any more right to be proud than his son or grandson who, amid all the great changes of industrial and social life, has held the farm true to its old-time tradition? No, we do not think so. In some cases it has been harder to adapt the farm to the changes that have gone on all around it than it was to cut it out of the forest. Yes, farming to-day requires more intelligence, a quicker insight, more patience and a surer grasp of details than ever before. Still, now as ever, the way to broaden opportunity and clear the farm of obstacles is to attack them bravely one by one, and never give up.

*

ON page 415 Mr. Cook alludes to the fact that the annual consumption of cheese per capita in the United States is but three pounds, while in Great Britain the consumption is 18 pounds per capita. He thinks that it would be an advantage not only to the cheese maker, but also to the consumer, if we could encourage a greater use of this nutritious food. Perhaps one reason why we do not eat a greater quantity of cheese is the poor quality of the article as offered in most small or local groceries. Few are the village stores where good cheese is in stock, and the price is usually quite out of proportion for its nutritive value. Lean, bitter and poorly ripened, it is no wonder that consumers find it indigestible, and eat of it but sparingly. It merely makes its appearance as an extra on the tea table or an occasional accompaniment of pastry, instead of forming a part of the actual meal. Cheese should be used freely in cooking, but the leathery filled or skim cheese has disgusted many who have tried to use it, and thus lessened the market for better materials. Plenty of good cheese is made; let us insist that it be supplied, and the home demand will surely increase.

*

A FAIR synopsis of the points covered by the Supreme Court decision in the Porto Rican cases is given in our news column. It appears that when territory is acquired by purchase or conquest it becomes a part of the United States. It does not, however, obtain the full rights enjoyed by the various States until given such rights by Congress, as in the case of Utah or Montana. Thus the supreme power of the land is vested in Congress, and the President merely executes its will. The most important business question involved in this decision was the right of the Government to levy and collect tariff duties on goods brought from Porto Rico. If that Island were as much a part of this country as Maine or Nevada it is clear that any such tariff would be unjust and illegal. The Court decides that since the Island is not yet a State of the Union Congress has a right to fix tariff laws to govern imports from it. American producers of beet sugar, hemp, tobacco, wool and fruits fear the free imports of these products from the Spanish islands. They have argued that when this territory came under the American flag their business would be at the mercy of cheap foreign labor. It now appears that Congress has the right to regulate such imports in case it is evident that free trade would be injurious to the American farmer.

*

DR. E. E. HALE is credited with saying: "If you should take 12 prize-medal men from Harvard and put them in a sinking ship, they would all drown from inability to construct a raft." That is probably true, though it is not likely that one in 1,000 of Harvard men would ever be placed in any such situation. It would puzzle even the most "practical" man alive to make a raft on a modern iron ship! Prof. H. M. Cottrell puts the idea in another way:

> Travelers say the world is full of men who have taken a good general college training, and who have spent thousands on their education, who are glad to get places as walters at lunch counters or as motormen on street cars, while as soon as a man has fitted himself to feed skim-milk calves successfully half a dozen men are waiting to hire him at good wages.

We know from experience that educated men are obliged to take hard and humble jobs at times, but they do not always stay at the foot. Unless there be moral and mental force in the man, the most practical training on earth will never save him. The calf feeder may be so mean, hateful or dishonest that he would even make kickers or "robber cows" out of his calves, though they excelled in size and shape. Are we not overdoing this "practical" business? It has got to the point where Comptroller Coler, of this city, is reported as saying: "In my opinion, the city is better served where there is a man who is not very moral, but who is very smart, than by a man who is absolutely honest but very ignorant." We do not say that there is anything in the great hustle and push after a practical training that should weaken character, but let us remember that the ability to earn a great salary is not the whole story.

THE Massachusetts State Grange has gone into the insurance business. It assumed control of an old mutual fire insurance company, and seems likely to make a success of it. One of our readers thus states the case:

> Of course they do not insure all farm property, only that of members of the Grange, thereby avoiding the most undesirable risks, although they do not refuse to insure desirable village property. While farm property may not be so well protected in case of fire as other property, we consider that the buildings belonging to the members of our organization are as good risks as any others. Our order is composed of intelligent, prudent and careful people, thereby reducing the risk from fire, and we also consider that the moral risk is less than it is with average people.

For several years now many of the regular fire insurance companies have refused to insure farm property. In such States as Michigan and New York farmers have taken the matter into their own hands, and organized coöperative companies, which have been very successful. Organization! That is the watchword everywhere. Organization—not for aggression, but for defence!

*

IT is quite common to find farmers who complain about the wrongs of society. They say that competition, crime, the trusts and other things have created a dangerous class of citizens. Children are growing up in ignorance or with wrong training, who will prove a menace to the country unless they are given a better chance. Much that these farmers say is true. The towns and cities contain thousands of orphan or neglected children who will be left to grow up as best they can, or what is not much better, start life in some "institution" or reform school. Whenever we hear farmers talk about such things we feel like asking them what they are doing to remedy the trouble. The children are here. They cannot be made into good citizens by mere talk and complaint. What they need more than all else is home and home influence. Some of these very farmers might well take one or more of such children and bring them up. That would be true public service—a duty to country and humanity. Not only that, but many a discontented and unhappy farm couple would find life beautiful and ennobled by giving home and love to a child.

*

BREVITIES.

As one who waking in the night
From off the pillow lifts his head,
While o'er him comes a sudden dread,
And yet he dare not seek a light.

And so he will not search it out;
There may be naught, he does not know,
But lest to surety doubt may grow
He lies and hugs his trembling doubt.

O anxious soul, by thoughts oppressed
Of that dread future, far, yet near,
Cease to essay the question here;
Death will respond or else give rest.

—The Lantern World.

LIME lightens low land.

HOW is Ruby Queen doing?

THIS will be a great year for the hay tedder.

WE advise a small trial of Cowhorn turnips in corn.

DISAGREE with people if you must, but don't fight over it.

AN awful season, this, for the people who sell or rent bicycles.

NO, grass cannot grow on rain alone—it must have sunshine.

THIS is bad weather on the contents of the small farm ice house.

WE cannot find a single plant of our Winter oats. They paid their cost last Fall in pasture.

LEAVE the table wishing for another slice, and you will find the wish change to joy that you did not take it.

THINK of a man foolish enough to attempt to conquer the forces of the world before he can conquer himself!

WHETHER it's a question of exportation, consumption or digestion it is always the little surplus that spoils the trade.

A TEAMSTER in this city whose horse was poisoned with cyanide of potassium was ready to swear that "snide potassum" was used.

IS government organized for the benefit of the poor man? Not especially, but he ought to have an equal chance with the rich.

TO get the most out of lime do not put it on the surface after grass or grain has started. Put it on after plowing and harrow it in before sowing the seed.

LAST year the people of this country sent the Chinese $833,710 worth of ginseng. No doubt about it—if we could get them to take that value in American apples all hands would be better off.

ATTENTION is called to the description of the soiling system practiced at the New Jersey Experiment Station. The first article is printed on page 413. We hope to follow the crops right through the season.

ANTHROPOLOGY is the science of man—the study of the human functions and body. A professor of anthropology in Chicago says that a man who parts his hair in the middle "displays unmistakable evidence of a degenerate instinct."

Events of the Week.

DOMESTIC.—Thirteen lives are reported lost as the result of the floods in Tennessee. At Elizabethtown nearly 100 homes were destroyed, and at Watauga there was also heavy loss. In North Carolina there was also much damage, many cottages being flooded at Biltmore, and Asheville being shut off from railroad communication. The Cliffs Hotel, on the Catawba River, near Hickory, floated down the stream. . . . . The Presidential party started home May 25, the remainder of the trip being abandoned on account of Mrs. McKinley's health. . . . . Two electric cars racing for a switch, while going in opposite directions at Albany, N. Y., May 26, came into collision; five persons were killed and 40 injured. . . . An explosion in the Richland mine, Dayton, Tenn., May 27, caused the death of 17 men. . . . . The schooner C. H. Hackley, of Milwaukee, was lost in a gale on Lake Michigan, May 24; seven men drowned. . . . . The Tennessee River has flooded thousands of acres of land, and it is estimated that the farmers near Huntsville, Ala., have lost $100,000.

ADMINISTRATION.—The United States Supreme Court has decided that the Porto Rican tariff act is constitutional. A synopsis of the decision is as follows: Territory acquired by this nation from a foreign power is part of the United States. The right to acquire territory involves the right to govern and dispose of it. When acquired by treaty, the territory is subject to the disposition of Congress. While a part of the United States, Porto Rico and the territories do not come within the Constitutional provisions relating to unrestricted commerce between the States or the relations of the citizens of one Commonwealth to those of another. The Constitution is applicable to territories acquired by conquest or purchase only when and so far as Congress shall so direct. The power to acquire territory by treaty implies the power to prescribe upon what terms the United States will receive its inhabitants and what their status shall be in "The American Empire." The people of the acquired territory are not subject to the merely arbitrary control of Congress, but are entitled, under the privileges of the Constitution, to be protected in life, liberty and property. The Foraker act is constitutional so far as it imposes duties upon imports from Porto Rico. The Supreme Court adjourned May 28 until the October term without announcing decisions in the remaining insular cases. This is interpreted as meaning that the court does not consider the status of the Philippines as parallel with that of Porto Rico. The Government intends to continue collecting duties upon Philippine merchandise. Solicitor General Richards believes that the President is free to govern the Philippines under the Spooner act as their needs may require. . . . . The Platt amendment was accepted by the Cuban Constitutional Convention, May 28, by a vote of 15 to 14.

PHILIPPINES.—Reports from Manila show that there has been much laxity in commissary methods at Manila, in spite of the arrangements made for inspection. An easy opening for fraud—and one which must have seemed apparent from the beginning—was the privilege granted to civilian employees to buy foods of the commissary for their messes. These goods, it appears, have sometimes been bought in larger quantities than needed, and the surplus sold to outsiders. As Uncle Sam sells commissary goods at cost, and as such things are sold at very high prices by Manila merchants who import them, handsome profits were easily realized. . . . . The prosecution against D. M. Carman, Senor Carranza and others accused of trading with the insurgents, has been abandoned. The military authorities consider that although the convictions of a number of Manila merchants would be practically certain were the investigations continued their prosecution would be inexpedient, as the consequent damages to business would outweigh the good accomplished. Provost General Davis, who has reviewed the testimony in the Carman cases, said to-day that while Carman could be convicted of trading with the insurgents, it would be unjust to punish him when nearly every trader in Manila is guilty of similar practices. . . . . A new army scandal has developed in southern Leyte, where several officers have been arrested on the charge of trading in permits to ship hemp from closed ports in that Province.

GENERAL FOREIGN NEWS.—The proposition of the American Government to secure a reduction in the war indemnity demands against China to $200,000,000 has been unanimously rejected by the representatives of the other powers, who will insist upon China paying the full amount claimed—$337,000,000. A despatch received in London from Pekin says that the Government of the United States will under no circumstances consent to any increase in the Chinese tariff, unless commercial advantages are conceded in return. . . . . At Waldenburg, Prussia, May 25, 21 miners lost their lives as the result of fire in a coal mine. . . . . May 24, an explosion in a Welsh colliery entombed nearly 100 miners; 70 lives lost.

FARM AND GARDEN.—Consul General Mason, at Berlin, has informed the State Department that the official German crop report gives a discouraging outlook for German agriculturists. A long and severe Winter and tardy Spring is held to account for a very bad year in crops. In a number of districts from 50 to 90 per cent of the whole Winter wheat failed. Clover has fared badly.

John Z. Miller and Joseph Levering, general manager and superintendent of the Harrison Butterine Company in Kansas City, Kas., were arrested May 22 by A. E. Prescott, a deputy United States marshal, charged with violating the Federal laws for regulating the manufacture and sale of oleomargarine. Specifically, the two officers of the Harrison Company are charged with defrauding the Government in using oleomargarine stamps twice, an offense for which unusually severe penalties are prescribed by the oleomargarine laws and internal revenue regulations. However, from the nature of the cases, it is an open question as to whether the men are really guilty of willful and intentional violation of these Federal laws and regulations. It is charged that large quantities of oleomargarine, returned to the Harrison Company as spoiled or damaged, would be removed from the pails and the pails refilled and shipped out again under the same stamps. The revenue officers contend that this is a violation of the law, as under no circumstances can a pail, package or revenue stamp be used a second time, no matter if the contents are spoiled or unsalable. Inspector McCoy, who has worked up the cases, claims to have evidence to show that upwards of 100,000 pounds of oleomargarine have been returned to the company since last September, while the records show that a comparatively small amount of this had been reported to the revenue office. The tax is two cents a pound. The penalty for violating the oleomargarine stamp laws includes confiscation of the manufacturing apparatus, together with oleomargarine and raw materials on hand, besides a fine not less than $500 and imprisonment for not less than six months.

The Orchard grass seed growers of Kentucky and Indiana, where about 75 per cent of the crop is raised, will combine again this year in the marketing of the crop. This was decided on at a recent meeting of 32 growers held at Goshen, Ky. Twenty-eight of those present voted to combine and to place the business in the hands of P. W. Hardin, of Louisville. Mr. Hardin states that indications are for a shorter crop this year than last, and attributes this to the drought of last Fall and the decrease of acreage, which has been made necessary by the tiring of the land from successive crops. He thinks growers will receive more than $1 a bushel for this year's crop. Growers claim combination is made necessary by what they allege to be a league among dealers to refuse to buy seed till it is offered at their price.

The American Seed Trade Association will hold its annual convention in Rochester, N. Y., June 11-13.

The fourteenth annual meeting of the Florida State Horticultural Society opened at St. Augustine May 21.

Six months in jail and a $10,000 fine is what it cost Albert T. Dow to make bogus butter and swindle Uncle Sam out of the revenue thereon. Dow conducted an illicit oleomargarine plant at 2334 State St., Chicago, Ill., called the Fertile Valley Creamery Company. He received cream daily and sold it without the trouble of transforming it to butter. The revenue office asserts that it was defrauded of $40,000 in special taxes on oleomargarine. The fine was promptly paid and Dow's lawyer pleaded to have the jail sentence set aside. Judge Kohlsaat refused. The fine is the heaviest ever imposed by a United States Court in Chicago.

Broom corn valued at $200,000 was burned in Chicago May 27 by a fire which destroyed a warehouse. The broom corn was owned by W. L. Rosenberg, a Chicago manufacturer. The building, which was valued at $25,000, was owned by the Cortland Wagon Company, of Cortland, N. Y.

The Governor of New York has appointed the following delegates to the Farmers' National Congress at Sioux Falls, October 1 to 10: Geo. L. Flanders and Fred J. H. Kracke, of the Department of Agriculture; Elliot B. Norris, Master of the State Grange; Senator Henry S. Ambler, Edward A. Callahan, Frank E. Dawley, Geo. A. Smith, Gilbert M. Tucker, Wm. D. Barns, Dr. Henry G. Piffard, Frank Urner, W. H. Hallock, Benjamin A. Babcock, J. J. Dillon and W. E. Dana.

CROP PROSPECTS.

Nearly all of the smaller fruits have blossomed abundantly. Apples quite well for the off year, with the exception of R. I. Greening. F. E. D.
Shoreham, Vt.

The fruit trees of all kinds are blossoming very full, and look now as though we would have a full crop. Plums fair and cherry blossoms are falling; apples are just in full bloom. H. F. W.
No. Ferrisburgh, Vt.

Apple, pear and cherry trees blossom full. Very few plums raised here, on account of black knot. It has been impossible properly to spray trees on account of rain. Our fields are flooded; potatoes that are planted are rotten. E. W. M.
Essex, N. Y.

We never saw old potatoes so scarce at this date, as at present. This fact, with South Carolina new crop so seriously injured by drought, and North Carolina's diminished acreage and storm injuries, the outlook presents strong assurance of very high prices for North Carolina and Virginia crops. S. H. & E. H. FROST.
New York.

The prospect for apples seems to be good, with the exception of the Baldwins; there is promise of abundant crops of cherries, peaches, plums and pears. The Winter grain never was put in the ground in poorer condition than last Fall, but I never saw it looking generally better than it does at this writing. E. V. A.
Columbia Co., N. Y.

From the outlook there will be an abundance of fruit of all varieties with the exception of apples, which will not be more than one-third of a crop at the best. Not wishing to count chickens before they hatch, I have waited to see the blossoms rather than guess at the buds. Where are those who prophesied a drought? I would like to have stood them out this forenoon.
Applegate, N. Y. H. I. S.

The fruit in this section wintered fairly. The cherries bloomed abundantly, the variety a small red, a native with us. There are not many of the English varieties near here. The pears are full where there are live trees. The apples alternate here quite a little. The prospect for grafted Winter fruit is small. Spitzenburg is especially naked; Spy also, though our Spies have lost their bearing qualities; Baldwins are (part of them), very full. The peach trees have no blossoms this year; last year they were very full. G. T.
Buel, N. Y.

About a week ago apple blossoms began to appear. Rain has fallen nearly one-third of the time; about a day of misty weather, and for two or three days cool; mercury 45 to 55 degrees; little wind with the rain. Apple raisers and apple buyers are fearing bad effects from the continued rain. A ride of 120 miles the past week along the orchards of Monroe, Genesee, Orleans and Niagara counties makes me think that the estimate of apple men, that the bloom this year is not equal to more than one-third of last year, is about right. I have seen but two and hear of but half a dozen orchards with a bloom of the average of 1900; have seen perhaps a dozen orchards with a half of last year's average blossoming. Curl-leaf has developed on peach trees in this county very fast during the past week. I saw none on peach trees in the western part of Monroe County. Pears seem to be setting full. Wheat and grass are looking fine. It is so wet in some parts of the county that only about one-half of oats are sown that were planned for.
Orleans Co., N. Y. N. C.

Apples show up now about in the order named: Twenty-Ounce, Russet, Snow, Cat Head, Hubbardston, good; Greening, King, light; some Baldwins where none last year; a few Spies. Pear, plum and cherry white with bloom; peaches light. Five steam sprayers, each said to have capacity of 1,800 gallons in 10 hours, have started within a radius of three miles of me this Spring. Everyone acknowledges the necessity of spraying, and there will be more done than ever before, but rain is bothering us just now. W. J. S.
Albion, N. Y.

The prospects for fruit are fairly favorable in this section of western Rutland Co., Vt. and northern Washington Co., N. Y. The early varieties bloomed the fullest. The Winter fruit will not be as much as last season. Plums and cherries bloomed full, also pear trees. There will be abundance of strawberries, field as well as garden berries. Some farmers sprayed when the fruit trees were in bloom. They seem to have the best results. Some of the farmers have their potatoes and corn planted, but most of them have not planted all their corn yet. Those on low land will have to wait for dry weather, as the wet season has been a setback. Pastures are looking fine. I never saw a better prospect for grass at this time of year, especially on newly seeded. Old hay is being bought up and pressed. One man has a contract to load 25 cars. Benson, Vt., furnishes the most. Oats are looking well. Wheat looks fine. I am trying a piece of Ohio beardless barley; it is growing well, for it is on a side hill. J. S. C. P.
Fair Haven, Vt.

CROP AND WEATHER REPORT.

During the past week crop growth in all sections east of the Rocky Mountains has been hindered by the cold. In the central valleys corn is coming on very slowly. The stand in Nebraska and Iowa is fair, and cultivation is in progress. Planting is finished except in New England and the North Atlantic States, where the constant rains have prevented farm work of all kinds. Wheat in the Mississippi and Missouri Valleys needs rain, while in Maryland, Virginia and North Carolina the crop is suffering from an excess of rain. Fly damage is reported in Kansas, Missouri, Illinois and Michigan. In Texas harvesting is in progress. In the Ohio Valley the oat outlook is promising. Cotton conditions have improved, except in the Carolinas, where it has been injured by floods. Tobacco transplanting is going on rapidly. Plants are abundant except in Kentucky, where they are scarce and small. The western apple prospects are not so favorable as before reported. Apples are dropping badly. The latest reports on this crop in New York indicate a slight improvement. Flood damage in the Carolinas and Tennessee is greater than was at first thought. The lowlands are flooded and the high ground badly washed. The crops of some farmers have been entirely wiped out.

In Delaware fruits of all kinds are late. Blooms on tree fruits, including peaches, is heavy. Strawberries, while at least 10 days late, will be fair. Blackberries were injured by the cold Winter. Early potatoes are coming on in good shape. For some time the Florida pine belt has been in great need of rain. This condition is now relieved, and there is promise of a full crop.

In spite of all that has been said about the superiority of Sicilian lemons to those from California, trade in the latter is moving along in great shape. A train of 10 cars, which is said to be the first straight trainload of lemons ever sent from California for the East, is on its way to New York. The whole crop is estimated at about 2,500 cars.

The northern Georgia peach crop will be large. A number of orchards will give their first crop. Shipments of early varieties will begin shortly after the middle of June. Elbertas will not be ready for six weeks or more.

The strawberry outlook along the Hudson Valley is quite promising, with the exception of those on wet ground, where the plants have suffered from the excessive rains.

The financial condition of farmers in the Wilmington section of North Carolina is said to have materially improved during the past two years. The causes are the high prices of cotton last year and the development of the trucking industry. Truck farming worked hard and well managed has eaten up a good many mortgages in the Carolinas and Virginia.

Cantaloupes from North Carolina.

What varieties of cantaloupes should be grown in North Carolina? What size of package would you recommend? What stage of ripeness should they be gathered? Would you advise shipments by refrigerator or open freights, cost considered, from this State? T. B. P.
Hillsboro, N. C.

We receive a great many cantaloupes from North Carolina, and we find the best method for packing is either in third-barrel baskets or a crate similar to the California orange boxes. The best varieties are the Netted Gem, Rocky Ford and Jenny Lind. We would not advise planting any other but these three. If shipped in refrigerator cars they need not be picked until they are almost ready to part from the stem; if shipped by open freight they should be fully mature but not ripe. If ripe they will not carry. ARCHDEACON & CO.
New York.

The Eastern Shore of Maryland.

Farming here is not done on such an extensive scale as in the days of slavery; many of the larger estates have been subdivided into smaller farms, many of which have been purchased by the northern and western settlers, and to-day produce 10 times as much as in former years, when trucking was unknown. The most successful farmer raises a combination crop; he keeps his herd of Jerseys, has two or three acres in strawberries, peach orchard, and from two to 10 acres for canning houses, pears and tomatoes, also asparagus. Last year the pea crop was a failure, on account of the louse. We have a good prospect for large fruit crop. Along the salt water rivers and Chesapeake Bay a failure in peach crop is unknown, especially on the low lands, which are subject to periodical inundation. We have quite an advantage here over the remote northern and western settler, especially in point of climate and market, being within easy access of Washington, Baltimore, Wilmington, Philadelphia and but seven hours to New York City by rail. In one of your recent issues I noticed a picture of an English walnut tree. They grow large and vigorously wherever cultivated above tide water. I know of some very old and large ones; one owned by an old woman brings her about $25 a year. G. T. B.
Cambridge, Md.

Woman and Home

From Day to Day.

THE HARD-TO-PLEASE.

There ain't no pleasin' people on this bloomin' earth below;
In the meltin' days o' Summer they're hollerin' fer snow!
An' when the snow comes siftin' through the winders o' the sky,
They're hollerin' fer Summer an' weather hot an' dry!

It's this way on the hilltop, it's this way on the plain:
"The craps are gittin' dusty; good Lord, send down the rain!"
An' when the rain is failin' an' weather's lookin' rough,
It's "Wonder if they'll drown us? We done had rain enough!"

There ain't no pleasin' people, no matter what you do—
No matter what good fortune, they growl a lifetime through;
An' when they leave this country to seek the final lot,
Heaven won't be cool enough fer them, an' t'other place too hot!

—Atlanta Constitution.

*

HERE is a bit of wisdom from the Straight Edge: "'Bear ye one another's burdens and so fulfil the law of Christ,' means a whole lot more than simply condoling with people in their mental troubles. The law of Christ's kingdom of social and industrial righteousness is to bear the burdens of life's drudgery, and to find ways of relieving those burdens for the largest possible number of people who are laboring under them."

*

THE medical authority of the Chicago board of education asserts that in investigating child study in the public schools he traces dull and weak children back to their infancy, and finds that in most cases they were bottle-fed babies. The Illinois Child Study Society holds that the naturally nourished infant has a better chance by at least 30 per cent than the bottle baby in getting a good start in life. If the bottle were only resorted to as a necessity there would be little cause for comment; unfortunately it is, in too many instances, an effort to evade the responsibilities of motherhood.

*

WE read recently of a small girl who has a way of thinking out things for herself. The other day, when her father asked her to mail some bills that she had chanced to see him making out, she refused. "It's against the law," she said. "Why, I've seen it up everywhere on the fences and telegraph poles—'Post no bills under penalty of the law.'" The same little Jane one day visited one of the upper grades at school, where the teacher was reviewing a class in physiology. Many times she reviewed them on the channels of the blood, the class responding in unison, "Arteries, capillaries and veins." Jane's memory seldom plays her false, so her account of this might be taken as an object lesson in faulty enunciation.

"My blood-vessels are R-trees, caterpillars and worms," she announced glibly at home. "I s'pose it's the trees what makes me grow."

*

CRETONNE-covered boxes for storing clothing in a bedroom are no novelty, but there is one new idea in their making this year, and that is the use of large ornamental brass or bronze hinges on the outside of the lid, instead of the small hinges hidden inside. The lid is fastened by a large hasp matching the hinges, which are just the style of those seen on medieval coffers. The box is upholstered in flowery cretonne, and lined with some delicate color. Such a box is an excellent thing to hold shirt waists, and is quite an ornament in a room. It is not beyond the ability of a home carpenter, though quite expensive to buy readymade. Exceedingly flowery cretonne and chintz are very popular for upholstery and hangings this season; they are usually in demand for Summer homes. Many of the furnishings specially designed for the Summer homes of city people are equally appropriate for the farmhouse. For example, among floor coverings are the Hindu dhurries, rugs woven in a blanket-like texture of worsted and jute, in stripes of red and deep indigo blue. Their usual size is 4x7 feet, and their price ranges from $1 up. Chinese cotton rugs provide another inexpensive material; they are woven like the Smyrna rugs, in pretty patterns of blue and white, green and white, and brown and white; they are very inexpensive, and wash well. Split hickory and rush furniture, made after the old-fashioned models, is now very much the mode for country homes; it is painted and enameled in various colors, or left without any treatment. A farmhouse furnished after the style of a city man's country home will

3727 Fancy Waist
32 to 40 in. Bust.

be pretty and artistic, without being necessarily expensive.

*

VEGETARIAN restaurants are already successful in several cities of the old world; they are not so well known here, in spite of the American tendency to seek after new things. A lunch-room of this class recently opened in New York is hardly a restaurant in the common acceptance of the word; it is headquarters for a coöperative industrial enterprise called the Straight Edge. The people of the Straight Edge, who are trying to apply the Golden Rule to business and social life, say that the problem of getting the ordinary work of cooking, serving meals, washing and scrubbing done without making somebody drudge and slave and be regarded as a "menial" is undoubtedly the biggest problem that coöperative industry has to tackle. Without making any efforts towards a vegetarian propaganda they demonstrate that a well-cooked and tastefully-served meal of vegetables can be provided for a small cost, and to the satisfaction of its partakers. The bill of fare is headed by the motto: "Nothing that ever squealed." The meals are varied day by day, consisting of three or four vegetable dishes, corn and wheat bread, dessert, and tea, coffee, cocoa, etc. A sample bill of fare consists of creamed sweet potatoes, corn fritters, boiled onions with spinach dressing, Straight Edge bread, and spiced fruit pudding. The cooking is excellent—the bread, made from meal ground purposely after the old process, beyond all praise. After lunching in a hurried business restaurant of the ordinary type, with an atmosphere like the tents of Kedar, it is a small slice of the millenium to partake of this "dinner of herbs, where love is." It will be interesting to watch the outcome of the experiment.

3815 Three-Piece Skirt.
22 to 30 in. waist.

The Rural Patterns.

The fancy waist illustrated which, combined with the skirt below, will make a very handsome suit, is made from satin Aiglon in pastel pink with revers of cream guipure over white, soft, full front of white chiffon, and simulated waistcoat of pink panne with band of white ornamented with small jeweled buttons. All soft-finished materials are, however, equally suitable; for odd bodices taffeta, crêpe de Chine and all the familiar soft satins, as well as lace are used, and costumes made from any one, as well as from the simpler henriettas, cashmeres and foulards are eminently appropriate to the design. The foundation is a fitted lining that closes at the center front. The back proper is seamless, but is joined to the fronts by means of under-arm gores. The fronts are plain and turned back to form revers. The full front, or plastron, is attached to the right side of the lining and is hooked over on to the left, and the simulated vest is stitched to position beneath the revers. The sleeves, as shown, are tucked above and below the elbows, but left free to form puffs at shoulders, elbows and wrists, where they are finished with bands of lace, but, if preferred, they can be made plain, the pattern for the lining only being used. To cut this waist for a woman of medium size 4¼ yards of material 21 inches wide, or 2¼ yards 44 inches wide, with ¾ yard of chiffon for full front and ⅝ yard for simulated waistcoat, will be required when tucked sleeves are used; 3¾ yards 21 inches wide, or 1¾ yard 44 inches wide when plain sleeves are used. The pattern No. 3727 is cut in sizes for a 32, 34, 36, 38 and 40-inch bust measure; price 10 cents from this office

A tucked hip yoke is seen on many of the new skirts. All the lighter-weight wools are peculiarly adaptable and such soft silks, cottons and linens as foulard, louisine, crêpe de Chine, taffeta, cotton grenadine, embroidered muslin, batiste and the like are charming. The skirt is cut in three pieces, a narrow front and wide side gores. The fullness at the upper portion is arranged in the graduated tucks over the hips, but is laid in an inverted pleat at the back which provides graceful folds and ample flare at the lower portion. To cut this skirt for a woman of medium size 6¼ yards of material 21 inches wide, 5¾ yards 27 inches wide, 4¾ yards 32 inches wide, 3⅞ yards 44 inches wide or 3⅞ yards 50 inches wide will be required. The pattern No. 3815 is cut in sizes for a 22, 24, 26, 28 and 30-inch waist measure; price 10 cents from this office.

An Act of Insubordination.

PART I.

Grandma Doane stopped rocking and sat up very straight. "Did you say that Sarah Sherwood is living in the old place?" she demanded eagerly.

Mrs. Prescott sat by the other south window sewing. "Yes, Mother," she said placidly, "she's lived there all Winter. The old man, Mr. Griffin, died in December, and Luella didn't want to stay there any longer. The old place was left to Mrs. Sherwood, and they came out to live there. Ellen and Mattie live with the old folks. Mr. Sherwood isn't very strong and seems a good deal older than she does. Ellen never was married, and Mattie is a widow. They don't like living there any too well, it's so quiet, but they are just as good to their mother as can be. I'm so glad she is going to spend her declining days in peace and quiet in the house where she was born."

Mrs. Doane had not paid strict attention. She was folding her work with nervous fingers; now she stood up with a determined motion. "If Sarah Sherwood is living in the old place, I'm going straight up there."

Mrs. Prescott looked up quickly. "Why, Mother!" she excialmed, "you must be crazy. It's three miles."

"Not by the old path," Mrs. Doane insisted; "it isn't more than a mile that way."

"It's too late to go to-day, anyway," said the younger woman. "It's almost sunset, now. Besides, a mile is too far for you to walk. I'll take the horse some afternoon and we'll both go up and call on her," she ended with an air of calm finality.

Mrs. Doane sat down submissively, but her face did not show submission; it was rebellious and determined. Her daughter noticed that she seemed absent-minded that evening, and that her face was flushed and her eyes bright. "I do hope she isn't going to be sick," she thought. When she asked if she was not tired, her mother agreed almost eagerly and went to bed very early.

At a quarter past five the next morning the back door of the Prescotts' house opened softly, and Grandma Doane stepped out. She had on bonnet and shawl, and in her hand she carried her shoes and rubbers. After closing the door noiselessly behind her, she sat down on the stone step and with quick motions put on her shoes. When she was all ready she stepped off stealthily, walking on the grass instead of the path, that the crunching of the gravel might not betray her. When she was safely out of sight of the house windows she walked with more assurance, and laughed softly to herself.

It was early April and the morning was clear and cold. The last year's grass and roadside weeds were white with frost, and where the ground was soft it was shot through with anchor frost. Down the road went Mrs. Doane till she came to a wood path which she entered. "There!" she said when she had followed it a few rods, "I guess I'm safe. Nobody saw me, I'm sure. Now I won't have to hurry so."

She passed through a young growth of hard wood, and came to a clump of pines, where the ground was soft with needles. Once she heard the slow beat of a partridge's drum. She paused to listen and it seemed to her that her heart beat faster and faster, in unison with the accelerated measure of the bird's wings. Soon she came to an open pasture, where were rocks and stumps and huckleberry bushes. On the top of one of these perched a song-sparrow, and its sweet voice thrilled the listener; she stood still a long time, her eyes on the bird, and when she went on she stepped softly that she might not lose a note. And now she came to a fork in the path which she did not remember. She hesitated a moment, then took the most trodden one. The way seemed strange, and before long she came to the pond and a gunner's duck stand. "This is not the way," she said, and she hurried to retrace her steps and make up for the time she had lost.

On and on she went through the once familiar path, and at length she came out at the end of the lane which led to the Griffin place. The sun was rising, and its warmth was most welcome, for in spite of her brisk walking the keen air had chilled her slightly. Up the lane she walked more slowly that her eyes might take in each familiar sight. Everything was as she remembered it. The old orchard on one side, the beautiful level mowing field on the other, the garden farther up at the back of the cornhouse, and then the old red barn with its hospitable open shed facing the south. Everything was familiar, even to the turnstile that let one out of the barnyard, and, yes, it squeaked when she went through it just as it always used to. Then she saw the old red brick house; that was the same, too, except that they had built a little veranda at the back door. On the veranda stood a woman. She was tall and straight, and the sunlight fell on her white hair. She looked doubtfully at the woman who was hurrying toward her, then as she came very near she gave a little cry and ran quickly down the steps.

"Mary Trent!" she cried.

"Sarah Griffin!"

And then their arms were about each other. In the first moment of meeting, the years fell away and each called the other by her maiden name.

"I've run away," Mrs. Doane explained as her friend drew her into the house. "I'm going to stay all day with you. And Sarah, I came away without my breakfast, and I'm pretty hungry."

Mrs. Sherwood laughed. "When I first saw you do you know what I thought? I said to myself, 'There's some poor tramp that's been out all night, and I'll give her a cup of coffee.' I'll get you something in two minutes. Just take off your things and find a chair."

She stepped about briskly, getting breakfast for her guest. "I'm specially glad to see you to-day, Mary," she said, "because I'm all alone. Mattie has been off on a visit for a week, and Father and Ellen have gone to the city for a day's shopping. They hesitated about leaving me, but I promised to go to the neighbors', though now you've come I won't have to. They've only just gone, and I was watching them out of sight just as you came along. There—draw up your chair and go to eating, you poor, hungry tramp," and she patted Mrs. Doane affectionately on the shoulder.

When the meal was finished Mrs. Doane arose with brisk determination. "Now, Sarah," she said energetically, "I'm not going to be made company of to-day. I want to work, and you've got to let me. I don't want to complain of my folks and the way they treat me, but they forget that you can get tired to death of resting."

"That's just it," agreed Mrs. Sherwood. "I feel the same way."

"Well, then, we've got the whole day before us. What shall we do? Haven't you got some big piece of work you want to do? Something that's too hard for you and that you ought not to do?"

"Oh, Mary!"—Mrs. Sherwood's eyes sparkled and her cheeks flushed—"there's a quilt I've wanted to tie for a long time, but the girls wouldn't let me. They think it's better to buy the ready-made ones. I've got the batting and the lining all ready. That's just the thing for us to do. Let's hurry and get the work done."

They were putting away the last of the dishes when there was an impatient knock on the back door. They started guiltily and looked at each other, and Mrs. Sherwood went to answer the summons. A boy stood there. His face was anxious and he was breathing hard.

"Mother sent me up on my bicycle to see if Grandma's here," he said.

"Yes," said Mrs. Sherwood, "she is here and she's going to spend the day with me."

"All right," said the boy. "Ma said if she was here to tell her that she'd come up with the horse and get her this afternoon. She'll start at four."

"Very well," said Mrs. Sherwood, "I'll tell her."

"You are safe," she laughed, when the boy had gone. "I'm afraid we are very bad children. I must have caught it of you, for I was all right till you came. But just now I had the strongest desire to tell your grandson that I hadn't seen anything of you. I knew it wouldn't do, though. Now let's get at that quilt. You can carry the chairs into the other room and push the table into the corner while I go up to the attic and bring down the quilting bars."

SUSAN BROWN ROBBINS.

MOTHERS.—Be sure to use "Mrs. Winslow's Soothing Syrup" for your children while Teething. It is the Best.—*Adv.*

Laundering Starched Clothes.

In the first place, wash shirts and collars spotlessly clean; then dry on line same as other wash, and when perfectly dry use the following cooked starch. The exact amount of starch cannot be determined; about four level tablespoonfuls to quart of water. The nice point is to make starch just thick enough and not too stiff to rub in linen easily, about like cream before it begins to thicken in churning. Have on hand white wax; it can be bought at any drug store, and gum arabic dissolved in water and bottled. Ten cents worth of each would last an ordinary family a year.

Dissolve starch in as little cold water as can be used and still work it all down to smooth paste; then add boiling water, stirring all the while, until thin enough. Add to one quart of starch one-half teaspoonful of gum arabic, and with a case knife scrape off a small quantity of white wax. It does not readily dissolve in even boiling starch, so scrape it off thin. Use about half a teaspoonful of these shavings, set your starch on stove cover, and boil moderately for half an hour. Have a starching board, one that you use for this purpose and no other, using any wood that will not stain when damp. Our Washington fir is good, but cedar would not do at all. Turn shirts wrong side out and leave so until all is ironed except bosom. To starch, put collars and cuffs, one by one, in starch, just as you take it off stove. With a silver spoon you can move them in starch until they are completely covered. Let them remain until you have shirt bosoms all finished. To begin on these use the starch hot and with spoon spread starch first on right side of bosom, fold together and take bosom on wrong side and give the same twisting motion you do when wringing clothes. This forces the starch through linings, which is very important, for unless this is thoroughly done the bosom, instead of being stiff as a board, will be covered with blisters. Repeat on wrong side, only do not turn when you wring, for if you do all your work on wrong side of bosom you lessen the chances of leaving some soiled spots. Practice will soon show you when you have material full of starch, under pleat and linings. When all is thoroughly worked full of starch place wrong side of bosom directly on board, and with the fingers on right side rub out free from wrinkles. Remember any that you fail to remove now will remain just so when ironed. Treat cuffs of shirt in same manner; then hang on chairs very near a good fire so as to dry fast. Have a room free from dust. Work the starch in cuffs and collars as directed for bosom of shirt, and dry in the same manner until perfectly dry. I don't try to iron the same day, and always starch enough at one time to last a month or two; then they can be put in clean bag and ironed as convenient.

To dampen them for ironing don't sprinkle or dip in cold starch, as you will by so doing spoil all your work. Take a pail or pan full of water, dip shirt flaps in, wring out as dry as you can by hand, lay directly on bosom, wring out another cloth of same thickness and put on other side of bosom, then lay shirt cuffs on top of this damp cloth. Pile layers made in this way one on another, place starching-board on top with irons to weight it down, and in two or three hours the linen is just right to iron. Have the irons clean and smooth, and always have a cloth of beeswax to rub them on. Then always iron the backs of shirts first and make sure your irons are perfectly clean before ironing bosom. Have a bosom board; I use starching board with a flour sack drawn over it. You can put on a beautiful polish on linen starched in this way, and when you consider that your linen will wear twice as long and look well until ready for the wash you will think it as easy a way as the old. It certainly will furnish a number of polished surfaces to reflect back the pride of feeling that the family linen couldn't be told from city laundry work. MRS. KITTIE GRANT.

COME AND GO

In many forms

Rheumatism
Neuralgia
Lumbago
Sciatica

make up a large part of human suffering. They come suddenly, but they go promptly by the use of

St. Jacobs Oil

which is a certain sure cure.

Corns removed free. Send postal for trial box of A-Corn Salve Giant Chemical Co., Philadelphia

Dietz Junior Lantern (Cold Blast)

is the best one we know of for use around the house, stable, barn, cattle shed or in the cellar.

It is small and compact (only 12 inches high), handsome, durable, convenient and SAFE, and gives a large and beautiful white light.

It is made on the Cold Blast principle and will stay alight in any wind.

Price (expressage paid by us), Tin, $1.00. Brass (satin finish and lacquered so as to stay bright), $2.00.

Send for booklet. R. E. DIETZ COMPANY,
Established 1840. 87 Laight Street, New York.

MARKETS

NEW YORK, JUNE 1, 1901.

GRAIN.—Wheat trade has been active. Kansas prospects not as good as at first thought. Corn receipts at shipping points light. In oats both local and export trade are heavy.

BUSINESS BITS.

PARAGRENE has now been on the market long enough to be thoroughly tested, and it gives good satisfaction. On Hope Farm it proved satisfactory for Potato bugs. Samples and circulars of Fred L. Lavanburg, New York.

A FENCE that is really ornamental is desirable about any residence. Kokomo Fence Co., 454 North St., Kokomo, Ind., offers 25 designs of all-steel ornamental fence, which is cheaper than wood. The catalogue gives full information—ask for it.

A GOOD combination for a thrashing outfit is a Rumley engine and the new Rumley thrasher. These thrashers are equipped with all the latest improvements and labor-saving devices. The engines are made for burning coal, wood or straw, as desired. Write to M. Rumley & Co., La Porte, Ind., and they will be glad to mail you a catalogue.

NEW YORK State Veterinary College, Cornell University, offers free tuition to State residents; also 18 scholarships, each $200 a year, are open to competition by freshmen. The splendid equipment and unprecedentedly thorough and practical course should attract students to this new and promising profession. Entrance on regents' veterinary students' certificate, September 17, 1901.

SCRAPS.

YOUR article and illustration of carrying children to school was fine, and just what is wanted in this town, where politicians make a business of trading candidates, and hang to the old district system. Our farmers do not come to the front as their fathers did in by-gone days, and this rural picture of happy school children riding to school may help the mothers to act in this matter. J. R. C.

Connecticut.

AN APPLE SHED.—During the past two seasons I have put up a temporary apple shed by purchasing 12-foot matched boards, with which I make a lean-to shed on the north side of the barn. A piece of furring on the barn is all that is required to catch the top end of the board, and I leave the nails so that they may be pulled out. At the bottom some posts are set, and a piece of joist is nailed to them to hold the lower end of the boards, and in such a shed, 25 feet long, I can keep 100 barrels from the weather, and the sun will not shine upon the roof.

Rhode Island. F. T. JENCKS.

THE CROW NUISANCE.—No sooner do practical husbandmen cry down the crow than up starts the theorist who tells how many insects a crow's crop has been found to contain. Our native song birds are growing noticeably fewer year by year. The crows are growing more bold in their depredations; but I have not noticed that insects are any less. Crows seem to be chiefly occupied in stealing the eggs or young of our old-time favorites, many of these insectivorous. I question if these would not, if allowed to grow unmolested, do far more to keep down insect pests than do the crows which destroy them. Let us have a bounty upon the black rascal, as a necessary means of saving our useful birds. F. W. P.

If you find a cold creeping on, keep a bottle of Dr. D. Jayne's Expectorant near at hand, and take a little dose occasionally. It will relieve at once, and soon bring about a cure.—*Adv.*

Horses, Cattle, Sheep and Swine

$2 Book for $1

We have yet some copies left of a lot of slightly shelf-soiled books of **Horses, Cattle, Sheep and Swine,** by Curtis, that we will mail postpaid as long as they last for $1. This book is the standard work on live stock. It is used as a text-book in almost all agricultural colleges, and is indorsed by all leading authorities on live stock. It is a large book, fully illustrated, and requires 16 cents to pay postage alone. These copies are in condition for any library, and will be reserved for subscribers alone. They will not be sent at this price to dealers. They are a great bargain at the price for anyone who wants to make a study of animal husbandry.

THE RURAL NEW-YORKER, NEW YORK.

The New Horticulture

BY H. M. STRINGFELLOW.

We do not hesitate to say that this is one of the most interesting books on horticulture that ever was printed. Most reading farmers have heard of the now famous "Stringfellow Method" of planting trees, but few understand clearly what it is. This book tells the whole story in clear-cut, forcible style, which all can understand. Not only is the theory of close root-pruning carefully explained, but the general principles of gardening and fruit-growing are discussed. Mr. Stringfellow is a practical gardener, and he gives his own experience. We commend the book to all without reserve. New Edition, paper covers, 50 cents.

THE RURAL NEW-YORKER, New York.

Market Briefs

PICKED UP HERE AND THERE

A FISH ITEM.—What is supposed to be the largest cargo of fresh fish ever landed has just been unloaded from a vessel at Gloucester, Mass. There were over 200,000 pounds, 150,000 pounds being cod.

SLIGHTLY MIXED.—At the Registry Department of the New York post office a man called for a letter and was told to sign his name on the receipt card in the usual place. He then did some something that probably not one person in a million could do without considerable practice. Taking the pen in his left hand he wrote his name backwards. People standing by looked on curiously, but the man paid no attention to them, and evidently that was his usual way of making a signature.

A NEW FODDERING PLACE.—A man who has opened a small restaurant near THE R. N.-Y. office advertises the fact by means of a sign man who walks around the streets carrying a big canvas sign containing his announcement, name and business motto, which is: "Live and Let Live." It is a relief to know that he does not intend to season his food with Paris-green or strychnine, and that the results of patronizing him are not likely to prove immediately fatal. He evidently means well, but in his effort to appeal to the economical sense of the hungry crowd, has overlooked the fact that there are other lines of business for which this motto would be more appropriate than for an eating-house.

HEAVY GAME SEIZURE.—The law explicitly states that, even though game birds are killed in the open season, it is not permissible to put them in cold storage and offer them for sale during the closed season. The mere fact of having in one's possession during the closed season game birds protected by law, is considered a misdemeanor. State Game Protector Overton recently made a big haul in a cold-storage place in this city. Several thousand game birds were found, enough, it is said, to make a fine of $200,000 if assessed to the full extent of the law. The birds were partridge, quail, grouse, etc. A sample of each kind was taken for evidence and will be turned over to a naturalist to decide the species. At this writing the matter has not been closed up, and there is nothing definite to be said as to fines.

DOCKAGE CHANGES.—The Norwich and Stonington lines of Sound steamers have for 20 years occupied docks at Pier 36, North River. Their lease expires the last of this week, and it is said that the Dock Board has given them notice that the lease will not be renewed. It is evidently the intention of the Dock Board to lease this pier to some transatlantic line and force these Sound steamers to take dockage in the East River. This action comes as a great surprise, and has brought out many protests from merchants and shippers. Pier 36 is near a great business district dealing extensively in the dry goods, shoes and other articles of New England manufacture. In fact, many business houses are in this section largely because they wish to be reasonably near the docks to save trucking long distances. Also this is convenient for the produce commission dealers, who get considerable stuff from these steamers. These people consider that the Dock Board is acting in an extremely arbitrary manner in peremptorily ordering the steamship companies to get out without in any way consulting the interests of the business men who are located in that section. The task of trucking these goods from some pier in the East River across the city is enormous.

FRUIT NOTES.—There is a big surplus of miserably poor strawberries from North Carolina. In going through the markets an occasional crate of fine berries is seen, but they are the exceptions, the bulk on hand at this time being inferior on account of their small size, some but little larger than field berries; or, worse yet, the soft and rotten condition in which many have arrived. In nearly all the fruit houses men are seen picking over the berries and throwing away the poor ones, and in some instances the condition is so bad that they do not sell for enough to pay the freight. Wholesale prices on ordinary lots have been as low as two cents. A very fair grade of picked-over berries is retailing at 10 cents per short quart. The baskets, however, are not marked "short," and this short-package law seems to have frozen out during the Winter. A few North Carolina cherries are seen, some bringing as high as 60 to 75 cents per eight-pound basket, but the bulk received thus far is inferior, and not to be compared with the California cherries, which retail at 12 to 25 cents per pound. There is now and then a small lot of gooseberries, but this fruit does not attract much attention, and the canners usually get the most of it. One fruit man on Washington Street had five watermelons (the first we have seen this season) for which he asked $2 apiece. Judging by their appearance we should say that this would be but a fraction of the amount a man would have to spend for the doctor, and perhaps worse, if he were so rash as to buy one of these melons and let his children help themselves.

W. W. H.

BARN PASTURE FOR COWS.

A Well-Arranged Soiling System.

One of the most interesting dairy farms in this country is located at the New Jersey Experiment Station at New Brunswick. Prof. Voorhees, the Director, is a very practical man, and he has devoted the greater part of the farm to an experiment for providing cheap forage for a large herd of dairy cows. The old idea of providing one or two acres of pasture, over which a cow must roam in order to obtain her food, has been proven to be a back number at this Station. The farm is providing the rough forage for more than one head of stock for every cultivated acre. The cattle are given a small inclosure in which they exercise during a part of the day. The green forage is cut and brought to them, and a succession of forage crops must be provided in order to furnish this barn pasture from the middle of April until the middle of October. Two silos furnish a fine quality of silage for the Winter months, and stand ready to fill any gap made by failure of field crops. On May 28 I went to New Brunswick, so as to be able to tell R. N.-Y. readers just how this soiling system is operated. They had just finished cutting the wheat from two acres, and this and two acres of rye have furnished green food for the stock for May. As soon as these four acres were cut, plows were put at work turning over the stubble, and, as soon as the weather permits, cow peas of the Wonderful variety will be sown. At the proper time these cow peas will be cut so as to fill a niche in the soiling system, the remainder being cured as hay, and then the ground will be plowed again and planted to fodder corn. This will produce a good crop before frost, and, when it has been cut and fed green, wheat or rye will be sown for next Spring's feeding. At the time of my visit, Prof. Voorhees said that he had already green forage for 50 cows and other young stock, enough to last until the middle of July. This meant the Crimson clover, which was seeded in last year's corn; the first cutting of Alfalfa, which, on the day of my visit, stood 30 to 36 inches high; three different sowings of oats and peas; and an acre of mixed grasses, which are to be cut and fed if needed. The first planting of corn had also been made, although the stand was poor on account of the wet weather. In order to understand just what this system means, I will give the following table, which shows how the crops were fed last year:

Kind.	Date of seeding.	Period of cutting and feeding.	Yield, tons.
Rye	Sept. 6, '99	May 1- 4	4.1
Rye	" "	" 4- 7	3.4
Rye	Oct. 12, '99	" 7-12	6.0

This explains itself, giving the date of sowing, date of cutting, number of days' feeding from each crop, and the full succession from May 1 to October 1. The crops are cut each day with the mower, loaded into wagons and hauled to the barn. As a definite and exact experiment is required, each load is carefully weighed, so that they may know the exact amount produced on each acre. This, of course, takes more time than would be required in a practical dairy, yet it is of great importance, as it gives the actual results. I will ask readers to study the table here given, and hope during the season to carry the crops through, giving the dates of sowing and cutting, the amounts of forage produced, and the results, so far as they are obtained, from time to time. There are many farmers so situated that at least a partial soiling system would be possible, and I feel sure that a visit to the Station and a view of the actual crops in growth would quickly show the advantages of producing this green forage. H. W. C.

THE STUDY OF SHORTHAND.

A reader wishes to know whether this is taught successfully by mail, and how best to practice at home. Yes, certain schools do good work in correspondence instruction in this line; but it must be remembered that really proficient shorthand writers are nearly as scarce as the proverbial hens' teeth. Authorities go so far as to say that there are less than 25 people in the world who are experts in taking down all classes of matter. The thousands who are called stenographers have merely a little smattering of some one branch of this trade, just enough to enable them to do fair work in writing letters, and in some branches of reporting. Through mail instruction the principles may be had, and also hints as to methods of study and practice, but the pupil will find that this word "practice" must be branded on his mind in italics or the biggest capitals. A reasonably thorough knowledge of the best usage in language is necessary. Two points to be aimed at are correct and readable word outlines, and speed. Many try to work up speed at the expense of readable signs and vice versa, instead of aiming to keep an even balance. Here are a few methods of practice for those working at home which we have found of service. Have some one read or talk to you, speaking as rapidly as you can possibly take it and read it afterwards, and gradually increasing the speed so that the writer will be worked to the utmost. This will get to be monotonous, but just such bitter doses, sometimes for an hour on a stretch, will be met in actual shorthand work, and one must be able to take them. A plan for acquiring signs for a good many words, and also some speed, is to take a newspaper, and over each word write the proper outline. Study the strange words and make the signs for them several times. Marked improvement in getting a wide vocabulary will be noted by writing a column a day in this way. Another helpful plan is to take a short newspaper article, read and make the signs for it sentence by sentence. Then lay it aside for a day and try to read it, referring to the original article only when necessary. Even a very limited knowledge of shorthand is of some service, though used only now and then in making notes. The study of it trains the eye, ear, brain and hand to work together. It is like a grindstone for sharpening up one's wits and making him think quickly. It also develops the memory, as in rapid work one will often get a whole sentence behind. He must at the same time be making the outlines for the previous sentence and still thoroughly grasp what the speaker is saying, keeping up this double-barreled performance until a pause of the speaker gives him a chance to catch up. No one need expect even partly to master this trade unless he is willing to go at it in dead earnest. There is no reason to be discouraged, however, for great difficulties and tasks that seem impossible on the start, melt away before careful, persistent work like snowbanks under an April sun.

THE GARDEN BOOK, by T. Greiner. The Farmer Co., Philadelphia, 190 pages; 50 cents. This is a very useful book calling especial attention to the need of every farmer for a garden or truck patch. Explicit and reliable directions are given for growing every variety of vegetable. The diagrams and plans for farmers' gardens are especially useful. A vast quantity of valuable information is contained between its covers.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

Bed-Time.

Going to bed to tumble and toss and dream; to pursue in vain the phantom sleep through long weary hours and rise to a new day unrested and unrefreshed. That is the way with many a woman, who is tormented by the aches and pains resulting from female weakness, and other diseases of the delicate organs of woman. Dr. Pierce's Favorite Prescription was made to cure just such cases and it does what it was made for. It heals ulceration and inflammation, dries debilitating drains, cures female weakness, strengthens the body, soothes the nerves and enriches the blood. It gives lasting strength for the day and sound sleep for the night.

"For three years I suffered continually," writes Mrs. L. J. Dennis, of 828 East College St., Jacksonville, Ills. "*I sought relief among the medical profession and found none*, until induced to try Dr. Pierce's Favorite Prescription. When I commenced taking this medicine I weighed ninety-five pounds. It built me up until now I weigh one hundred and fifty-six pounds—more than I ever weighed before. I was so bad I would lie from day to day and long for death to come and relieve my suffering. I had internal inflammation, a disagreeable drain, bearing down pains and such distress every month. But now I never have a pain—do all my own work and am a strong and healthy woman. Thanks to your medicine."

Biliousness is banished by the use of Dr. Pierce's Pleasant Pellets.

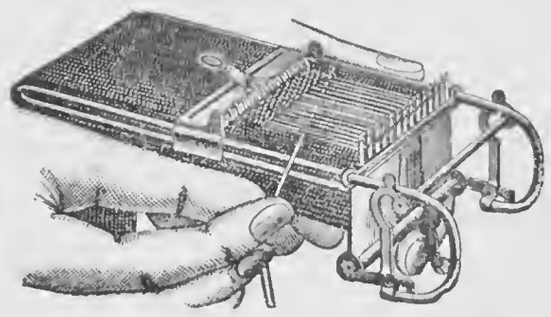
FARM PAPER FREE! Send ten cents to pay cost of mailing also names and addresses of five of your farmer friends and we will send you the Missouri Valley Farmer one year free. Regular price 50c. It is one of the best farm papers in the west and will tell you more about agriculture and live stock conditions in the great southwest than any other publication. It is filled with western stories and up-to-date articles in the breezy style of the west. Missouri Valley Farmer, Topeka, Kansas.

Gold-Shell Rings.

Most people like a nice ring. We show three styles. These are made by drawing a shell of gold over a rod of composition metal. They are better and will wear longer than solid gold rings of a low carat. The retail price would be from 75 cents to $1. We will send one of these rings postpaid as a reward for sending one new subscription at $1. Cut a slip of paper the size of finger and send for size.

A Darning Machine.

This is the only successful darning machine we ever saw. We have tried others that were absolutely of no value. This one is little short of perfect. It enables you to mend underwear, stockings, curtains, table linens, clothing, and does an endless variety of art and fancy weaving better, easier and quicker than



by any other way. Full directions accompany each machine. When a lady has once used this little machine, she would not do without it for any consideration. We will send it postpaid for $1, or for two new yearly subscriptions at $1 each. All money returned if no satisfied.

Live Stock and Dairy

REMEDIES FOR FLIES ON CATTLE.

The little fly is small indeed, but it requires comparatively few of these to make cattle lose in flesh and milk, and turn from quiet and sedate to wild and nervous animals. This has probably always been the case, but the advent of the little horn fly early in the nineties seemed to make a bad matter worse. These flies appeared in certain sections and clustered about the lower parts of the horns when they were not on the body proper, so that they were dubbed "horn flies." Much was written about them, and various remedies proposed or offered to the public. These pests in some pastures occurred on the cattle in immense numbers, and greatly worried them. While one reads less of these fly pests now than about five years ago, there is no doubt but that they are fully as common, if not more so, than they were then. They are much like the common house fly in appearance, only slightly smaller. The writer has employed various methods to reduce these fly pests. Several forms of manufactured fly killers are on the market, but these are very expensive, and have to be applied anew every three or four days, in order to keep up the effect. One of the very best of these is known as "Shoo-Fly." This has been extensively advertised, and great quantities undoubtedly sold. This is offered at 50 cents a quart by a local druggist of the writer's acquaintance. The 1901 *jobber's price list* of this preparation, which is before me as I write, quotes it at 60 cents a gallon by the barrel, or 70 cents by the 10-gallon lots. Fish oil, which in the writer's experience, is about equally satisfactory, is quoted by the aforesaid druggist at 65 cents per single gallon, or 55 cents in quantity.

If one has but two or three cows, one of these preparations may be very satisfactory, but it is a serious problem to handle a large herd, and the preparation means considerable expense and labor of application. This substance is applied with a wide, flat brush, or by spraying it on, the latter being the only practicable method with many cows. In our experience, a mixture of two tablespoonfuls of crude carbolic acid in a quart of fish oil, gave as satisfactory returns as the commercial preparations. One quart will do for one application on 40 to 50 cows. Pine-tar preparations have been used somewhat, but these are sticky, and their use is not to be recommended. The materials above referred to are intended to keep off flies, but not to kill them, they being offensive to insects. Pure kerosene, however, has an advantage, in that it may be sprayed on the cattle, and will kill many flies if it hits them to a reasonable extent. Each season we do considerable spraying of kerosene in the barns, thus killing immense numbers of flies. On the cooler nights flies collect on the ceilings and warmer spots in the barn, and then we dose them, using ordinary kerosene in a cheap hand spray, such as sells for 50 cents. We also spray them on the cattle.

It is a good policy to break up heaps of manure in the pasture, for the flies breed in these, and thus their development will be repressed. In any event, it is necessary to wage constant war against these flies, if one wish to get the best possible returns from either dairy or beef cattle. The suggestion to keep the cattle in the barn during the Summer days, soiling them there in darkened stables, and then turning them on pasture at night, is worthy of adoption by those situated to do so. Cows should thrive under such conditions. This fly question is a most important one, and the injury these pests do to dairy cows in depreciating milk yield is no doubt very great. Readers of THE R. N.-Y. who have successfully solved the problem at reasonable cost, would confer a favor on many stockmen by contributing their experience to its columns.

C. S. PLUMB.

HOW TO HANDLE ALFALFA HAY.

I find that wherever Alfalfa is discussed the question at once arises, can it be cured and made into hay? Having had seven years experience in making Alfalfa hay I will give some practical points in regard to it. Hay is said to be "grass cut and dried for fodder," and that is just about what the majority of the hay in the country is, having a variable feeding value, according to condition when cut and how the process of drying has been conducted. Plants give off most of their moisture through their leaves, and very little from the stalk. From this it will be readily seen that we must retain the leaves if we expect to get the moisture from the plant quickly. When the plant is growing it is supplied with moisture by the roots; when cut the supply is stopped, but evaporation continues from the leaves, and it quickly wilts. Farmers often say their clover is so heavy they cannot cure it. They spread it, turn it and perhaps run the tedder over it frequently, and finally bunch it up, but it will not dry out, but what moisture can be wrung from the stems by twisting a few of them together. All the time they have been stirring and tedding the clover it has been exposed to the sun, and the leaves being the most delicate part have withered and dried and been shaken from the stem before they could complete the work of carrying off all the moisture from the plant. After losing their leaves the stems dry very slowly, and are likely to mold when put in the barn. Such hay has little food value.

When about one-third to one-half of the Alfalfa plants show the blossom, you will find, if you examine closely, that there are yellow leaves beginning to show at the bottom of the stem. I think this about the right time to cut for hay. When in best condition cut at once; do not allow anything to cause delay, as it will become more woody and contain less digestible matter every day it stands, and you will not only lose in feeding value of the present crop, but will reduce the vigor of the plant, and the next crop will be lighter in consequence. This is one of the secrets of success; in short, Alfalfa should never be allowed to stand beyond the blossoming period if the best results are to be obtained. After cutting it should lie upon the ground undisturbed, from two to four hours, according to the weather conditions at the time, when it will be just nicely wilted; then rake and put into fair-sized bunches. Now, if the weather is good, let it stand two days, when it will be ready to put in the barn, and should be drawn at once without opening the bunches as is sometimes done. Handled in this way there is practically no loss of leaves. If you apply the test of twisting the stems to this hay you will not be able to wring from them much moisture, and yet there will be enough sap left to carry it through the sweating process in the mow without injury. But should the weather be rainy we have found that when well put up it will stand rain better than Red clover. I have had it stand in the field one week, when it rained nearly all the time, with no apparent injury except a little bleaching on the outside of the bunches. Never draw to the barn when there is any water on it.

Another thing I consider of importance is the use of salt on the hay when put in the mow. We use common salt which we buy in barrels. In using, when half a load is off level, the hay in the mow is sown broadcast with about two quarts of salt; then when the load is all off two quarts more are sown upon it. The salt will be dissolved by the sweating of the hay, and will prevent mow-burning or molding. When the hay is all in close the barn doors and have as little circulation of air as possible. As long as there is moisture over the top of the mow there is no danger of the hay spoiling; it will come out all right every time. Another feature of Alfalfa hay is, that when well handled it is never dusty, but makes the sweetest and most nutritious hay I have ever used for all kinds of stock, including hens. We feed practically no grain to our horses, only a little wheat straw to balance the ration, and they are always in fine condition and stand hard work without loss of flesh.

Tompkins Co., N. Y.

BUTTER FROM KAFFIR CORN.—A dispatch to the daily papers stated that the Overbrook Creamery at Lyndon, Kan., had lost $400 because the cows were fed on Kaffir corn. The Kansas Experiment Station, after investigating this case says among other things: "If Kaffir corn, which has been such a good yielder and drought-resister, should be excluded from the ration of the dairy cow, many farmers in central and western Kansas would be obliged to quit the dairy business. This would result in a loss of thousands of dollars annually. When the season is a poor one for the curing of the crop, and the grain has been left on the fodder, considerable penetrating dust arises from the crop when handled at feeding time. If the feeding is done just before or at milking time particles of this dust, with all the germs that they carry with them, will undoubtedly find their way to the milk pail, and may cause a poor quality of butter. In the instance of the Overbrook Creamery, the manager states that the Kaffir corn in that part of the country had all been damaged by rains, and where the feed was the poorest the milk from that farm made the poorest butter. Indications point to a slight decomposition of the feed. Hay and fodders of any kind contain large number of offensive germs, which if allowed an entrance into the milk pail and permitted to multiply rapidly, will cause a very undesirable quality of butter."

Horse Owners! Use

GOMBAULT'S

Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING. *Impossible to produce scar or blemish.* Every bottle sold is warranted to give satisfaction Price $1.50 per bottle. Sold by druggists, or sent by express, charges paid, with full directions for its use. Send for descriptive circulars.

THE LAWRENCE-WILLIAMS CO., Cleveland O.

Newton's Heave, Cough, Distemper and Indigestion Cure. A veterinary specific for wind, throat and stomach troubles. Strong recommends. $1 per can. Dealers, mail or Ex. paid. Newton Horse Remedy Co. (R) Toledo, Ohio.

ZENOLEUM Kills Lice, Ticks, Mites, Fleas, Etc., on all kinds of animals and poultry. Given internally it drives out worms. Cures all cuts, wounds, sores, etc. Non-poisonous. Endorsed by leading veterinarians. "Veterinary Adviser" free. Zenner Disinfectant Co. 100 Bates St. Detroit, Mich.

Cure Barren Animals

THE LOSS SAVED IS CLEAR PROFIT.

Others Cure their Animals, WHY BUTCHER yours? Thousands of cows, mares, sows, etc., restored to breeding in the past 20 years. The best stock farms in the world are our patrons, why not you? ABORTION: Every cow that aborts should be treated with this remedy. You cannot afford to experiment, profit by the experience of expert breeders. Treatment by mail, $1.10. Other remedies just as reliable. Ask for circulars any way.

DAIRY AND FARM NOTES.

Some Facts About Cheese.

GOOD FOOD.—People ought to eat more cheese; the Americans are a butter-consuming nation. We are much interested at times in furthering our export trade in butter, but when we are just about ready to talk with an exporter, domestic consumption increases and absorbs the surplus. Not so with cheese. We need an export demand in order to maintain an active market. While scarcely 10 per cent of our product is exported it is always the surplus that weighs down a market. Consumption could be increased one-half pound per capita; we should exhaust our surplus. We consume three pounds of American cheese per capita, while the English consumption is nearly 18 pounds. Think of buying a pound of steak that contains 70 to 75 per cent moisture, and paying 15 to 20 cents for it, rather than the same price for a pound of Cheddar cheese containing one-half that amount of water. We buy some fiber in the meat, and often a bit of bone. In the cheese not five per cent is waste, and the component parts, fat and casein, are the most digestible and nutritious of foods. Each year we are increasing the use of milk and milk products, which is an indication of good judgment. Much has been said and written about the indigestibility of cheese. It is my judgment that these conclusions have been drawn from skimmed or partly-skimmed cheese, and they are no doubt correct. The presently-accepted method of manufacture followed by the makers of northern New York is producing an article of food that is easily digested, and must soon be recognized as an everyday necessity. Only through the most rigid attention to quality can we hope to succeed in placing the cheese product by the side of meat as a daily food. I have often observed with what relish and haste a plate of soft, fine-flavored, silky-textured cheese would disappear from a hotel table; in fact, no food placed before guests will create more comment, favorable or unfavorable, as the case may warrant. THE R. N.-Y. has been instrumental in forming an Apple Consumers' League. I should like to establish a cheese consumers' league. By the way, the combination would be a good one, the fruit acid emulsifying the fat, and thus aiding digestion and increasing the consumption of two staple and honest products. While we are talking about foods I wish nervous people who are liable to have something the matter with them, or *think* there is, would eat less meat and more cheese, and drink a glass of milk instead of a cup of coffee, stick to it for a year, and report whether or not they have been benefited.

GOOD MILK.—The foundation of good cheese is good milk. It is well that a cow cannot comprehend what is said about her. If there is any trouble with milk at the factory it is often charged to the cow, when the fault was plainly with the owner or caretaker. I would rather trust a cow to do good work than the man who takes care of her. If the manufacturer could get milk always as pure and free from damaging bacteria as the old cow produces it he would have little trouble with his raw material. Probably no one item occasions greater loss among cheese factories and creameries, as presently managed, than taking in tainted milk. It not only injures the product, but decreases the output. Several causes enter into the case. Competition is sharp among manufacturers. Factories are built on every four corners, and farmers are inclined to be quite independent in their attitude; that is, some of them. Then again, makers are often indifferent, and fail properly to examine each can when emptied. During an apprenticeship which I served for 12 years at the weigh can, I found my weakness to be a lack of courage to tell a neighbor that his milk could not be used, and hence he must take it home. Some men have too much courage, and make patrons mad. If there is any one place that requires tact and a fine conception of the difference in human nature, it is at a weigh can. Where milk is purchased at a price arbitrary rules are posted and lived up to. Only a very small proportion of milk is purchased; the great bulk is manufactured on the so-called patron plan. Are the makers of butter and cheese keeping pace with the higher grade of goods demanded? I think they are. In market reports we read: "The quality does not seem to be up to former years." I have read it every year for 10 years. I have been eating butter and cheese through New York State and some eastern towns for eight years, and I positively know that the quality has steadily improved. Of course the consumer is much more critical now than then.

DANGERS FROM WHEY.—In the patron-plan factory the skim-milk and whey are drawn home for feeding purposes in the same can that hauls the milk. I have denounced the system at home and abroad, and have worked hard to inaugurate a plan which would do away with the evil, but nothing tangible has resulted. The farmers feel the feeding value of the by-product in our locality, and are anxious to have both the feeding and fertilizing value on the farm. They do not like to use a double set of cans, and I am not sure but as much harm would come to milk hauled in the same wagon with whey cans, by contact with germs, as comes to the milk from carrying the by-product home. The clean sharp lactic acid in whey or skim-milk does no harm. Lactic acid is a foe to the taint and gas-producing germs, the germs of an alkaline nature; germs producing a slimy or bitter condition. We use a clean, sharp lactic acid starter for butter and cheese to counteract the above troubles. Some milk in my experience and observation causes but comparatively little trouble. The farmer can see it; knows it is wrong, and willingly takes it home, but the other troubles mentioned he cannot see, and much less comprehends their evil effects. We have therefore adopted what seems presently the only alternative; that of keeping the whey tank thoroughly clean. A daily scrubbing with hot sal-soda water does the business, and it certainly has a marked influence on the character of milk as delivered. I am sorry it is true, but I have been in a great many factories, and it is the exception to find this receptacle in condition to keep whey or skim-milk clean enough to permit its entrance into a milk can. This plan adds much to the value of the by-product as a food. I have investigated the manufacture of whey and skim-milk into articles of commerce, and find every investigation bringing the same conclusion; that it is worth more to feed calves and pigs.

H. E. COOK.

Price of Milk for Butter.

What price should I pay for milk that tests four per cent butter fat to be made into butter at 20 and 25 cents per pound? The milk has to be taken two miles every morning and delivered into a separator. I keep the skim-milk. We run a private butter dairy, and as we can use more milk, I thought I might buy more milk as cheaply, if not cheaper than more cows and make it. Z. H. S.

Millis, Mass.

One hundred pounds of milk containing four per cent butter fat should make about 4½ pounds of butter; this selling at 20 cents per pound would bring 90 cents per 100 pounds for the milk. Counting three cents per pound for manufacturing the butter leaves 77½ cents received for 100 pounds of milk. It would probably not be too much for the one buying the milk to take 7½ cents from this amount, which would leave 70 cents per 100, which he could afford to pay for the milk, which on the basis of four per cent fat would be 17 cents a pound for the fat. The price that one could afford to pay for four-per-cent milk when the price obtained for butter is other than 20 cents can be readily worked out on the same basis. L. A.

KILLING FLIES.—After using several of the preparations on the market, I have settled down to the use of kerosene oil and carbolic acid; two ounces acid to gallon of oil. Put on as a spray, and for the purpose of killing the flies.

New York. CLAYTON C. TAYLOR.

UNMATE THE FLOCKS.—There is every reason why the males should be removed from the pens as soon as eggs are no longer wanted for setting. If not wanted for breeding another season their meat will never again be worth so much. Put them in totally dark but ventilated quarters, giving feed and light for a few minutes twice a day. In two weeks their flesh will have increased as much in tenderness as in fat. If left in the light they will keep on the move, and be too uneasy to fatten. A male just from the breeding yards is unfit for food. The flocks of hens will not be so mischievous without the male. The non-fertilized eggs are the only proper ones for putting down. These will keep from June to Thanksgiving with no preservative of any kind, but simply managing to keep the yolks from gravitating upward to the shells. Pack on ends, screw on cover, and invert firkins once in 10 days. Keep in a cool room.

F. W. PROCTOR.

THE "BEEF" HORSE.—The Live Stock Reporter has the following: "The beef horse—the heavy draft breed—is a profitable animal to grow upon all farms located within a corn belt. Pound for pound, he can be raised up to three years of age as cheaply as a steer, and if well bred and sound will bring seven cents a pound, while the steer will do well to bring five cents, and have to be fattened up to do that. The risk with the horse is a little greater than with the steer, but as a Winter cornfield forager he beats the steer all to pieces. This type of beef horse will be found to be the best for the average farmer to raise, as there is likely to be a continued demand at good prices for this kind of horse. A few men, natural horsemen, can perhaps do better in raising driver horses, but a special liking and knowledge of horses are necessary in this case, which are not required in the other. When this cumbersome Clydesdale animal gets old and decrepit, fat and lazy, and is just about automobile enough to walk into some illicit horse abattoir his top-heavy carcass will make a dangerous competitor in back-block quarters for poor grades of beef. He should be a cinch in old age in Germany for sausage manufacturers, where bolognas are born of any kind of meat."

THE FIGHT AGAINST MOSQUITOES.

UNCLE SAM LEADS THE BATTLE.

Effective Work on Long Island.

For years people have endured the stings and poisons of the deadly mosquitoes—not willingly, but because they knew no remedy. Now science is coming to their aid. Prof. L. O. Howard, of the National Department of Agriculture, issued a valuable bulletin on the mosquito and some of the best methods for fighting it. This has led people in various parts of the country to proclaim a destructive warfare against the insect. Considerable work of this sort has been done on Long Island.

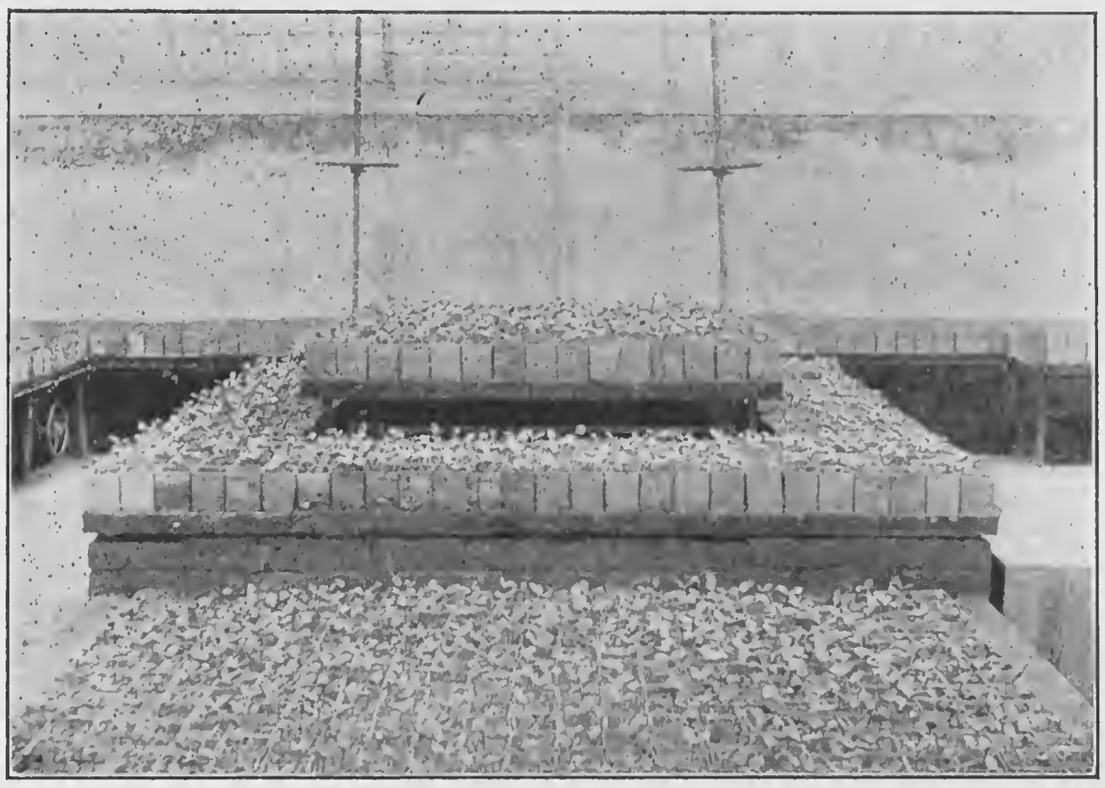
I have been fighting the mosquito practically in the way suggested by Prof. L. O. Howard's bulletin, and I consider the experiments outlined in that bulletin as practical and worthy of the attention of farmers and country people. I do think that mosquitoes may be, in the course of a year, certainly in two years' persistent and intelligent work, entirely exterminated from a given locality. It has been determined conclusively that malaria is not only transmitted by mosquitoes, but that malaria *cannot be* and is not transmitted in any other way! (See Prof. Celli's work on malaria, in which he traces the life history of the malarial germ, and demonstrates this point conclusively. (See also the works of Grassi and Ross on this subject.) Recently it has been proven that yellow fever is transmitted by a certain variety of the Culex mosquito, or what has lately been determined to be a distinct species of mosquito. While it has been demonstrated that these mosquitoes transmit yellow fever, it is not, as in the the case of malaria, the only means by which yellow fever is communicated. When the fact, which has long been known and frequently referred to by Prof. Howard and other eminent entomologists, is considered, that mosquitoes breed only where there is water, that they will not breed in absolutely salt water, the problem of exterminating them becomes comparatively simple. The female mosquito, as you will see by Prof. Howard's bulletin, lays from 200 to 400 eggs, which hatch out in the course of a week or 10 days, at Summer temperature, into little water creatures like minute tadpoles (larvæ). These creatures are obliged, it appears, to come to the surface every few minutes to breathe, and when deprived of this opportunity, will die in the course of a few hours. There are, therefore, three ways of attacking the pest. The first and best method is to drain all water or places where water will lie, even temporarily, for a space of 10 days or two weeks. Such large ponds as cannot be drained may be covered with a film of kerosene oil, a barrel being sufficient, if allowed to flow on the windward side of a pond, to cover three acres of water. As this will evaporate before 10 days or two weeks, the operation must be again repeated. Such ponds as are of an ornamental character and preclude the possibility of being treated with oil, can be filled with a species of fish which devour the mosquito larvæ. Sunfish, sticklebacks and top minnows are suitable for this purpose.

I am convinced from my observations and experiments that no pocket of water which exists as long as three weeks at a time is free from the liability, if not from the absolute certainty of breeding vast numbers of mosquitoes. As Prof. Howard points out, a single mosquito that has hibernated during the Winter in an old building, tree trunk or heap of leaves, will produce from four to six generations of 200 to 400 mosquitoes each in a single season. There are a number of varieties of mosquitoes, even on Long Island, and they differ from each other in habits and appearance as much as birds do from each other. I succeeded last year in eliminating them entirely from my property at Lloyds Neck, Oyster Bay, with the exception of four days, and the mosquitoes that then made their appearance were of a variety not bred on my property. I hope you will arouse the interest of your readers to the importance and practicability of exterminating this pest. I feel that they are as easy to deal with and control as is the spread of smallpox.

Long Island. W. J. MATHESON.

A NOVEL METHOD OF RAISING MELONS.

The illustration, Fig. 170, gives a partial view of the inside of a palm house which is being utilized as a forcing house for early watermelon plants. All the bench space is taken up with the closely-packed wooden boxes, as shown in the picture. There are 4,000 of these boxes, covering an area of about 450 square feet. The boxes are of cheap construction, each one consisting of but one piece, and having no bottom. They are four inches square by six in depth, and will each accommodate two or three plants. There being no bottoms to the boxes it is necessary to place them upon a wooden base of some kind to prevent the roots from penetrating beyond the space allotted to them. The soil used is a medium light loam. The seeds are placed in this the first week in May, and the plants are allowed to grow undisturbed for three weeks. The extended space between the plants and the glass in the forcing house causes the plants to grow spindly, so that it is necessary to harden them off in cold frames before they are placed in the open ground.



STARTING MELONS UNDER GLASS. FIG. 170.

After the plants have hardened off well, and the nights have become moderately mild, the boxes are carried to the field and ripped off from the plants as they are set out. Two boxes or four to six plants are allotted to each hill, but not more than three are allowed to mature. While this particular method would not be practicable as a commercial practice, a similar method could be followed profitably with an ordinary forcing house, allowing one to obtain marketable fruit from two to three weeks earlier than when the seed is simply planted in the field. E. A. B.

R. N.-Y.—Melons are sometimes started on sods or in metal pots, and taken to the field when of fair size. Last season we gained nearly 20 days by such. The metal pots used are those described in Ruralisms.

IS BEN DAVIS SELF-FERTILE?

What Other Varieties are Needed?

I have planted 400 trees of Ben Davis apples. These trees will be at least one-eighth mile distant from any other apple trees. Are they self-fertile enough to produce perfect fruit without planting some other varieties of apples with them? In any event, would they be benefited if other sorts were planted in the same orchard with them? What varieties would you recommend for this purpose, bearing in mind the fact that I only wish to plant red Winter varieties of apples for profitable results? I understand that the Ben Davis is a late bloomer, in fact, I am acquainted with only one or two Winter varieties of apples that bloom as late in the season as the Ben Davis. Would such standard varieties as Baldwin, King and Northern Spy remain in flower long enough to have a beneficial influence on the bloom of the Ben Davis? READER.

New York.

The Ben Davis is grown more than all other varieties combined in the Ozark region, and it is planted largely in blocks in which there are no other trees grown. It is self-fertile enough to produce perfect fruit without the assistance of other varieties. However, it is probable that the yield would be increased to some extent by having other varieties in the orchard, and where it can conveniently be done it is advisable to plant at least a few other trees here and there through the orchard. [Prof.] J. T. STINSON.

Arkansas.

We are not in the Ben Davis section here, and our trees of that variety are not far from other varieties. No instance has ever come under my own observation where it was proven that the Ben Davis did not perfectly fertilize itself, and yet I would not say that it might not be the case sometimes. We do not call the Ben Davis a late bloomer here; it is later than some and earlier than others, for instance, the Willow Twig and the Genet, but I would hardly know how to compare it with the Baldwin, King and Spy, as we grow them in such limited quantities. I generally practice and advise planting varieties so that they may fertilize each other, but more because I think there possibly may be times when it is necessary than from positive knowledge that it is so. L. R. BRYANT.

Princeton, Ill.

Many varieties of apples do not produce enough pollen to cause the best fertilizing of their fruits; besides, it is often better to have pollen from other varieties used for this purpose if it can be done. Sometimes it makes better fruit, and fruit of better color. In some localities certain varieties, like the Ben Davis, produce abundance of pollen, while the same variety in other localities will not produce enough to fertilize itself. Again, there are strains of Ben Davis which give enough pollen thoroughly to fertilize all its fruit, while there are other strains which are deficient. In southern Missouri the Ben Davis will fertilize itself in blocks of 100 acres, while in the very northern part of the State it will not. I do not know just how it acts in New York, but if there is any doubt at all, then plant two rows of Jonathan or York through the center of the orchard. L. A. GOODMAN.

Missouri.

I have no knowledge of stock injured by spray; heard stories of the kind, wonderful ones, years ago, when use of Paris-green was a new thing, but never any reliable account of trouble. I do not think it possible for such trouble to come from use of Bordeaux Mixture. Perhaps you will recall my writing to you a few years ago for advice about a cow of mine which drank as much as four gallons from the top of a barrel of Bordeaux Mixture. I did not have knowledge of it until several hours had elapsed. I then gave the cow 1½ pound salts, which showed their effect most decidedly, but I never saw any ill effect from drinking the Bordeaux Mixture. M. M.

Medway, Mass.

FARMERS AND FARM FIRE INSURANCE.

Discriminations in Favor of Village Property.

It is true that the insurance companies, some of them at least, are not anxious for farm property risks, and under their system of doing business I am not surprised. As I understand it, they depend upon agents chiefly to extend their business and make collections, the agents getting a liberal percentage on the money taken. Under this system the higher the valuation allowed on a building the greater the agent's fee, so there is the constant temptation on his part to value property for all it is worth, or even more. Provided the buildings are not burned the greater is the profit to both the company and the agent. When insurance is undertaken by the Grange I understand that only members of the order are admitted to the privilege, and as the members are all known to one another the risks are much less on the average than where the insured are unknown, as is the case with the officers of the regular companies, except the local agents who, as intimated, may be over-tempted to allow high values on the property insured. So far as I have learned the Grange insurance business thus far has been generally satisfactory to the members. They have saved money by their plan. Of course you know that insurance men are not doing business for either fun or charity, but to make money for themselves. So-called "mutual" companies are mutual to a degree only, as the officers have control of rules, rates and the size of their own salaries. I know of one agent, an assessor, who has often been asked by patrons when on his rounds, whether he was valuing the property as assessor or insurance agent? I am satisfied in my own mind that no building should ever be insured for a higher sum than it is taxed for. An insurance officer tells me that he dislikes farm property in this section because the business of farming is on the decline, and the property is constantly diminishing in value, so that the "moral risk" is too great. When a farm becomes unsalable and the buildings are insured for more than the entire property will readily bring the temptation to be careless about fires is too great. A really dishonest man may have it in his power to "unload" upon the insurance company at better rates than he could get in the real estate market or at private sale.

Insurance offices and officers are almost invariably located in cities or large towns, and in many portions of New England real estate is gradually rising in these, while in the strictly rural portions it is as gradually diminishing in its value. The farmers, as they view it, contend that the people of the cities and towns are partly to blame for this condition, as the laws are made to favor the cities. In most of the cities and large villages now the people are supplied with water under pressure, and have fire engines and other improved methods for controlling fires, so that insurance companies feel that the risk is much less than back in the country, where if a fire gets started it generally finishes the buildings, leaving little besides the cellar and well. It is not a little aggravating to farmers in the outskirts of a town to be charged higher rates for insurance than is charged on center of town property, when they have been taxed heavily to help pay for village water works, fire engines and firemen's salaries. Again, when they see an insurance officer in the center of the town receiving an annual salary for keeping the company books equal to or exceeding the value of a good farm in the country they cannot be blamed for looking about to see whether the insurance business cannot be run on a more economical scale. The Grange people, meeting together as they do every week or fortnight, can transact their insurance business at much less expense than is usual, when the work is done by agents who travel about the country soliciting business and often depending upon their commissions for a living. The members of the Grange, too, are, as a rule, rather a select class. They are more intelligent, more enterprising and less inclined to be careless in the care and management of their business. If this is true the risk on members' property would be less than on the general average, but insurance companies could hardly be expected to make distinctions in rates on these grounds. I do not know what responsibilities the State Grange has assumed by taking on the business of an old company. But I do believe that the organization can do an insurance business for its own members at a saving on the usual rates. It has already been done, which is pretty good proof. A. W. CHEEVER.

Massachusetts.

Insurance by the Massachusetts State Grange.

We insure farm property that is owned by members of the Grange and no other farm risks will be taken. We believe in the long run that we shall get a better class of risks by this method, and we desire to encourage farmers to join our order. We insure nothing but private dwellings and private barns and Grange halls, and contents of each of the foregoing. We insure dwellings and private barns other than farm property, whether the owner belongs to the Grange or not. I am aware that there is much truth in the claim of old-line companies in regard to excessive losses on farm property, but we believe that a careful selection of risks will enable us to overcome some of the difficulty. As one who has had considerable experience in the fire insurance business, I will say that one thing we most need is honesty of purpose by property owners. Too many cry up values to insurance agents and cry them away down to assessors. A law that would permit no man to insure his property for more than what he was willing to pay taxes on would be a feature which would tend to place more responsibility on property owners. Something must be done for the farmers in this matter of insurance, as rates are increasing to very high figures with lower dividends due to shorter terms, and many companies absolutely decline the property. The oldest company in our State (the Worcester Mutual) built up its business on farm property, but now declines to take a single new risk in that class, and is dropping many of its old patrons, either entirely or by dividing the amount with some other company. We hope the effort may be a successful one, and in any case do not see how our farmers can be any worse off with us than with others, and they may be much better. WM. A. HOWARD.

Sec. Mass. State Grange.

EDUCATING PURCHASERS AND CONSUMERS

We read a great deal in different papers about educating the farmer as to the proper manner of marketing his produce. Advice, in copious doses, is given as to how he should sort and clean his eggs; as to the proper manner of making, coloring and packing his butter; he is told that he should keep the small potatoes, the knotty apples, the inferior fruits and vegetables of all kinds at home, and thus receive more for the selected specimens than he would otherwise for the whole. One good thing about this advice is that it is cheap. To look at the produce that comes into the New York and other markets one can't help but feel that it is needed. But another class sadly needs advice, also, and that is the purchasers and consumers. While there is a demand, and I think an increasing demand for choice products, nicely and attractively packed, the majority of buyers are not yet educated to the point where they are willing to pay enough more for them to pay the shipper for the extra labor involved. This may be heresy, but it is the truth nevertheless. I don't advocate this careless assorting and packing, but I wish to present the other side of the question, and show that two parties need educating and not one as is generally supposed. I have seen buyer after buyer pay 25 to 50 cents per barrel less for a barrel of poorly-assorted, inferior fruit than he could have obtained choice fruit for. The extra quarter or half dollar looked so big to him that it shut out all appreciation of the difference in quality. Yet the best fruit was really the cheapest. I have seen buyers haggle over the price of a really superior article, claiming that they could get one "just as good" elsewhere at a lower price; and then failing to accomplish their object, return and pay the price demanded, thus belying the former assertions. The education needed here is evidently in the matter of truth telling rather than in appreciation of quality. Instances innumerable have been noted among the commission houses where produce of all kinds put up in good shape, and of superior quality, has not sold for enough more to pay for the extra labor involved. This is not because the commission merchant doesn't appreciate the extra value, but because the purchasers do not. Some commission men have worked up a trade that pays well for these choice products; many have not. The grower of fine produce must shun the latter and find the former.

I know of a shrewd Jerseyman who for years has shipped his large crop of potatoes to the New York market just as he dug them from the ground, little and big. When his commission merchant protests, he simply says: "Sell them enough cheaper to satisfy the buyer; I can't afford to sort them." He has learned that he gets more dollars from the class to whom he sells by following this practice. I know of two celery growers who had about equal areas of celery. One of them sorted out and threw away hundreds of dozens of rusted, slightly rotted and inferior roots; the other threw away nothing unless it was so bad that he couldn't hide it in the middle of a bunch. The same commission merchant sold both lots. The last mentioned grower received considerably less per dozen, but he had more dollars when all was sold. I know of a Michigan farmer who shipped beans to New York so dirty and full of worthless beans that one would think them unsalable. Yet they sold for only 15 to 25 cents per bushel less than they would have brought had they been thoroughly cleaned, not enough to pay for the loss in cleaning, not to speak of the labor. Similar instances might be multiplied indefinitely. Yet there is another phase of this subject that may perhaps excuse the purchasers somewhat. Some dishonest shippers have practiced deception in packing. A barrel faced with fine large Spy or King apples has been found to contain inferior fruit of perhaps half a dozen varieties in the middle. A barrel of potatoes of large size and beautiful appearance on top are half small, wormeaten and worthless in the middle. So with many products. Purchasers have been deceived so much that they conclude to purchase the lowest-priced thinking that they will thus lose less. Some fruit dealers, too, prefer to buy unassorted fruit, and assort and pack it to suit their trade. They make a fine margin by so doing. The whole matter in a nutshell is, that those who put their first-class products in fancy shape must find a market where the purchasers have been educated to the proper point, in order to get proper returns for their labor. What is needed is not less education for the farmers, but more for the purchasers. F. H. V.

INDIANA FARM NOTES.

ORANGE SORGHUM.—At Sheridan, Ind., the other day I called on George Symons, who has 55 acres of sorghum planted. He makes the best molasses in this section, and cannot near fill the demand. I was surprised to learn that he does not like the Orange cane. He uses the Honeydew. He claims that he has made up and compared tons again and again, and that the Honeydew will yield a third more molasses on an average. It also has a habit of stooling. This is not suckering, but stooling, like wheat. I asked whether the stooling stalks will ripen as soon as the central and parent stalk. He said that there is practically no difference; it sometimes makes it too thick and small, and it should be planted thin. This variety does not lodge worse than the Orange, and it does not have red cracked hearts so badly, and is not affected as much by rains just before ripening. It does not get as ropy; is clear of that tartish taste, can stand longer without cutting and will lie in the pile longer without souring. It seems that it has all the good qualities in one variety. Mr. Symons found it too expensive last year to strip it, and fed it through whole.

BAGASSE FOR SILAGE.—While talking he asked whether I thought the bagasse would keep in the silo. I said that if it were cut and carefully packed it would, but if piled in whole it would sour. He said that he had a plan in view of arranging for patrons having dairies or feeding steers to grow a field of sorghum, bring it to him, and have it milled and run on to a wagon and taken direct to the silo on the patron's farm. This would be getting a double crop from it. It would certainly be rich feed even after milling. All feeds containing much sweets or starch are hard to keep in a silo without souring, unless put in in a fine condition and tramped well. Then they keep as well as other feeds. Cattle eat the bagasse well now, but it is coarse and rough on the mouth; also very mean to handle. If one had the ropy stuff packed in a silo it would be hard to feed.

E. H. COLLINS.

As to stock of any kind being poisoned by eating grass in an orchard where Bordeaux Mixture or Paris-green has been used. I have never known of such a case; do not think there has ever been one in this locality. I have sprayed my orchard this Spring with Bordeaux and arsenic, making it very strong of the arsenic; had hogs in the orchard all the time, and cattle just a few days after the spraying. No harm has resulted. F. E. V. E.

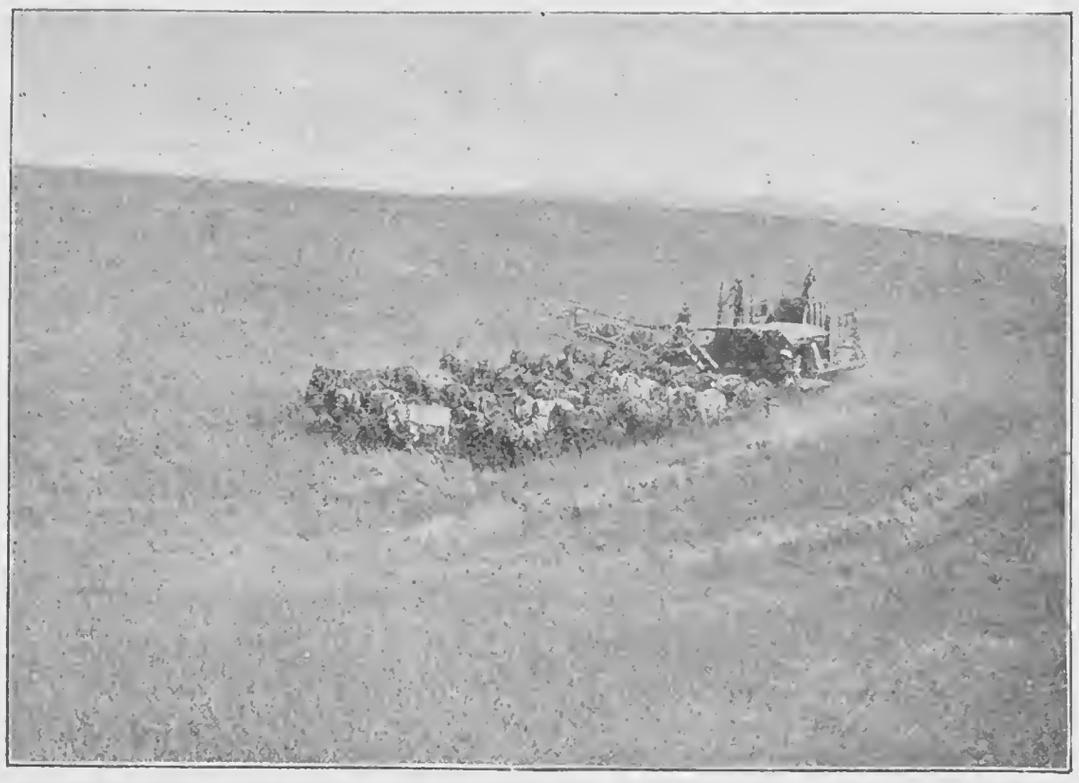
Stanley, N. Y.

THE NATION'S WHEAT FIELD.

Wholesale Operations in Washington.

Last week we gave a picture of a great wheat harvesting outfit used in California. Two more pictures are given this week—both taken from Bulletin 24 issued by the Department of Agriculture. Steam and gasoline are used as motive power for some of these machines, but horses and mules are also employed, especially on the rough and hilly fields. Fig. 172 shows a combined harvester and thrasher used on the hilly sections of California. There are 55 horses on this machine, which cuts the grain, thrashes it and leaves it in bags. Fig. 173 shows a smaller machine—a binder with a 12-foot cut. This is hauled by six horses which walk behind the binder. Of course, in these big operations, it is not considered important to get every head of grain or every straw. The straw is cut rather short, and there is a rush to cover as much ground as possible in a day.

The bulletin from which these pictures are taken gives an interesting account of the efforts made to improve American wheats. Certain improvements are necessary in the great western wheat-growing sections. For example, in the famous "Palouse country" there is an annual drought which occurs about two weeks before harvest time. This often causes the wheat to shrivel—hurting both quality and yield. An early ripening sort is needed. It is said that if some good variety could be produced—ripening 10 to 15 days earlier than the varieties now grown, its culture would add from $1,000,000 to $3,000,000 to the wealth of this one section. In like manner other sections require certain qualities in new wheats. The machinery for harvesting wheat has been wonderfully developed; the perfecting of varieties must follow.



HARVESTER-THRASHER AT WORK NEAR WALLA WALLA, WASH. FIG. 172

HARVESTING WITH WIDE-CUT BINDER NEAR COLFAX, WASH. FIG. 173.

NOTES FROM CALIFORNIA.

We have a fine prospect for a crop of good apples. The Newtown Pippins, White Winter Pearmain, Wealthy, Bellflower and Skinner's Seedling look exceptionally well. We shall have plenty of apples from the time Red Astrachans are ripe all through the season. So far no worms have appeared, although usually in thinning time we find plenty of them. We thin apples when they are as large as filberts if other work is not pressing. Bartlett pears are a failure in this section; other fruits except peaches are very light. Cherries are about one-fifth crop, and badly cracked by rain. The cracking of the cherries makes much work for the girls who pack them for shipment east, as every cherry must be looked over and any crack or imperfection in the skin puts it into the cull box, and when the proportion of culls is large it means less boxes for the packer, and therefore less wages, as they are packed by the box. No one dreads to see the rain more than the cherry packers, as it means more work and less wages. Cull cherries are sometimes sold in local markets, or dried. On the other hand, when there is a good crop and few culls the girls make good wages, and the work is not hard. When a box is completed the packer carries it across the packing room where it is examined by an inspector to see if it is properly marked on the end, with her initials and the number of the orchard. The packer's ticket is then punched and she returns to her place with an empty box which she wipes clean inside, marks her initials and number on the end and proceeds to pack. This getting up to carry the box and get checked is a rest from too continuous sitting. It might be interesting to know that it takes on an average about 250 persons to pick, pack and deliver a carload of 2,000 boxes in one day.

I am much interested in all I see in THE R. N.-Y. about hired help, for it is a continuous problem with us how to get good help, and by good help I mean men who have no bad habits and are industrious. I have worked out, and have also employed many men, and can say from an experience that covers a period of about 30 years, that the curse of the working people is bad habits, and the worst of all is laziness. On this place we draw the line at cigarette smoking and drinking. If a man chews or smokes a pipe, and shows a desire to get rid of the habit, we give him a trial. We have employed a number of soldier boys just back from Manila, and have found them generally very poor help and full of bad habits. I can truly say to any young man who is seeking employment on a farm, or anywhere else for that matter, put forth your best efforts with head and hands for your employer, work for him faithfully, honestly, and with your might. It is surely to your interest to do so. Every hour unnecessarily lost, and all carelessness either in work done or neglected, will hurt you worse than your employer. There is always room for the man who makes himself so useful that he is missed when he leaves the farm for a day. On the other hand, employers who attempt to grind their help in any way are not worthy of the name, and will surely lose by doing so. It pays to treat men well, both from a financial as well as a moral point of view. Make your actions and habits such that they will command respect. You will then be in a position to require decency and respectability on the part of your hired help. H. G. KEESLING.

California.

A CITY MAN TURNS FARMER.

PART VII.

The Rocks of New England.

After an interval of some weeks we open this subject again in order to answer some questions which have come from readers:

The city man who is looking forward to going on a farm some time, and who reads these articles, will be quite likely to have in his mind some questions perhaps like these:

What did you plant that next Summer after you bought the farm? What did you plan for a money crop? How many acres did you plow? What proportion of your hay and grain did you raise? How much did it cost you to live that year? In other words, "How did you get along?" "What mistakes did you make that I can avoid?" Most of the above questions are based on a misconception of this part of the country. One of the first questions asked by a visitor from Long Island, New Jersey or New York is, "Where is your plowed land? I don't see hardly anything but grass."

Dairying is the main business, and cream is the "money crop" of the great majority of the farmers here. Since the silo came into use more corn is planted than formerly, and some farmers raise 50 or 100 bushels of potatoes to sell, but nearly all depend on the monthly check from the creamery for means to buy what costs money. Nearly all the grain used comes from the West. I have heard it stated that at the two railroad stations where grain is sold in this and the adjoining town, over $40,000 was received in one year for grain, and this is a sparsely settled community. There are over 100 miles of roads in this town and the voters are less than 300. "Lazy farmers," you say? No sir! New Englanders are not noted for laziness, at home or abroad. Come up here and plow a piece of sod; then when you want to seed it down pick up the stones. You will need no other reason why more land is not cultivated.

But is this stony soil against New England? On the contrary, a prominent authority says that is the very reason that it can stand constant cropping for 200 years and still yield more bushels of shelled corn per acre than any other section. I have seen the United States statistics, which give 30 bushels per acre for New England and 27 bushels as the highest average elsewhere. Of course there are exceptions; land on the river, where hardly a stone can be seen, and pushing farmers who raise big crops, but the rule is as I have written. On the low lands, however, frost comes two to three weeks earlier, and as much later in Spring, so that those who want to raise peaches and tender things have to go to the hills. There is splendid air drainage among these hills, and water that fairly sparkles. A man will live 20 years longer up here than he would in the city. These mountains should be dotted with the Summer residences of the rich. Such scenery! I have stood on Willington Hill, and looking to the northeast, where great billows of hills, covered with the glory (no other word will answer) of their Autumn foliage, have brought tears to my eyes. G. A. C.

EVERYBODY'S GARDEN.

A WINTER JOB.—In an editorial, page 360, of THE R. N.-Y., this subject was so admirably discussed that it well deserves more than a casual reading. The problem of profitable Winter work is a serious one, and confronts the farmer and gardener alike. To those favorably situated for engaging in the work, I know of no more effectual remedy than growing Winter rhubarb. No costly structure or apparatus is required, and considering the cost of production there is no work for the gardener or small farmer that will give as large returns. The work of forcing is so simple that very little skill or previous experience is required, and being grown in the dark the work goes on regardless of the weather. Since discussing this subject two or three years ago the added experience only proves more conclusively the entire feasibility of the work. The enterprise is growing more extensive each year, and the profits are entirely satisfactory. Any gardener might be satisfied with a return of over $500 from one shed constructed simply of old boards and manure. Yet that was done by one of Detroit's enterprising market gardeners the past Winter. On February 15 a neighbor of mine sold a load of 172 dozen rhubarb to a commission merchant, at 50 cents per dozen, or $86 for the load. These are not fairy tales, but actual experiences. Of course the industry is yet in its infancy, and the question of demand, or a market for the product is a vital question. The history of tomato growing will answer this very readily. So we might recall the history of forcing lettuce, radishes, cucumbers, or any of the vegetables that have been taken out of their regular season and changed by forcing to a Winter produce. But all these require the use of expensive greenhouses, or acres of glass, while the finest quality of rhubarb is grown in the dark, at a very trifling expense, either for structure, or heating apparatus. Location as to market must be considered; also the root supply. As to the latter problem, begin preparing for the Winter's work now, by the careful culture of whatever roots you may have on hand; procure as many as possible from your neighbors, to be taken up after freezing in the early Winter. To many this enterprise may prove a very satisfactory solution of the vexing problem of a Winter job. J. E. MORSE.

Michigan.

I have always left my stock in the orchard when spraying and have never known of any being poisoned, although I have always been careful not to let a large quantity run out of the tank in one place. The bloom on our fruits would now indicate very few Baldwins, one-half crop Greenings, full crop Twenty Ounce, Pound Sweet, Roxbury Russet, Wagener, etc., full crop of plums, peaches, pears and grapes. More spraying is being done this year than ever before. More tent-caterpillars than I ever saw before, and people generally are trying to fight them. Canker worms are just commencing to hatch out. Wayne County fruit growers organized with a membership of 48 on April 6. We expect to have a Summer meeting on some of our farms this month. B. J. CASE.

Wayne Co., N. Y.

Farmers' Club.

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see whether it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

Blight on Quince Trees.

G. D., White House, N. J.—Last Summer some kind of blight struck my quince orchard and did considerable damage, killing four trees to the ground. Sometimes it affected the ends of branches, and in other cases it girdled the trunk or main branches. The bark seemed to die quickly. Only older trees were affected, and worst where the ground was moist and rich. I cut the dead parts away. If I see signs of it again this Summer will it help to spray with Bordeaux? What is the cause and remedy?

ANS.—The Quince blight is an old offender, and is apt to bring ruin. This blight is common to pear and apple trees, and there is no better remedy known than the knife. Cut away all the blighted parts, well below the diseased portion, and burn them. The worst plants should be entirely removed. The experiments in spraying for the fire blight have not been so successful as to warrant it as a profitable preventive. However, spraying hits other enemies of quinces at the same time, and might be done with hope of benefit.

BYRON D. HALSTED.
N. J. Experiment Station.

Velvet Bean or Cow Pea.

E. R. D., Barto, Pa.—Can I grow the Velvet bean to maturity or make a sufficient growth of vines, sown about June 15? It is a young orchard which I wish to sow with the beans, and in late Fall plow the vines under to fertilize a crop of corn in 1902.

ANS.—No. We would not advise the Velvet bean. With us the growth is too slow and small. It is a southern plant—not so well suited to northern conditions as the cow pea. Early Black or Whippoorwill cow peas sown by the middle of June will make a good growth. When they are plowed under we would sow rye for a Winter crop.

Dung Worms and White Grubs

W. S. M., Bellaire, O.—This Spring I set out about one acre of strawberry plants. Over one-half the ground I scattered cow and horse manure mixed before harrowing. This manure was fresh, having accumulated only about four weeks. When cultivating the plants the other day I noticed the cow manure under the surface contained numerous small dark-colored grub worms about one-eighth inch long. I wish to inquire whether these grubs are the very young of the grubs of the May beetle, and how came the eggs in the fresh manure which was spread about April 10 long before the appearance of the beetle itself? If not grubs of the May beetle, will they grow larger and attack the plants? I noticed quite a number of long flat black beetles which had holes made in the soil; also some very small beetles about one-eighth inch long.

ANS.—During 1895 and 1896 we discussed at considerable length the question if the true white grubs of May beetles lived in manure, or that plants could become infested with these grubs by the use of manure. We then requested all readers to send us any dung worms they might find, and several readers responded. But none of the dung worms sent was the white grub of May beetles, nor have we ever seen such grubs living in manure. We are quite sure that the small grubs found by W. S. M. in the rather fresh manure on his strawberry bed are the nearly full-grown grubs of an Aphodian dung beetle; the beetle is only about a third of an inch in length, and has red wing-covers and a black head and thorax. These little beetles appear early in the Spring and hover over and bury themselves in freshly-dropped or partly decayed manure in which they lay eggs; the grubs hatching therefrom also live in and eat the manure. If W. S. M. will put some of this infested manure in a box or some soil where it will not dry up, I think that by June 15 he will find that they will have transformed into the little beetles. As these Aphodian dung beetles do not feed upon living vegetation in any of their stages, infested manure may be freely spread upon any crop without fear of injury to the plants. The long, flat, black beetles noticed by W. S. M. were doubtless beneficial Ground beetles, and it is quite possible that the smaller ones were Aphodian dung beetles. We believe one need have no fear of introducing true white grubs or any other injurious plant-feeding insect into strawberry beds with manure.

M. V. SLINGERLAND.

How to Grow Large Melons.

T. W. F., South Bend, Neb.—Give what information you can about growing watermelons of large size. I find that manure increases the amount of vine, but not the size of the melon. I plant five feet apart each way, and thin to one plant in the hill. The vines cover the ground before any melons are ripe. I get lots of melons, but they are too small for market. What effect would it have to cut off the ends of the vine as soon as three or four melons are set?

ANS.—Size in watermelons is more a matter of variety than of cultivation. Of course the vine must be well fed to produce full-sized melons, and we have found a good chemical fertilizer containing eight and 10 per cent respectively of phosphoric acid and potash a useful adjunct to rotted stable manure, which is the foundation of melon growing. The fertilizer may be applied at the rate of two or three pounds to a hill before planting, well mixed with the soil several inches deep, or can be cultivated into the soil after the plants are up. The most effective way where the price of the product warrants it is to apply the fertilizer broadcast at the rate of 1,000 pounds an acre before planting. Pinching the ends of the vine and limiting the fruits from two to four according to strength of the individual vine, would certainly tend to increase size of melons.

What Is Asparagus Rust?

T. R., Trevose, Pa.—In your opinion, would sulphur be of any benefit to put on asparagus for the rust? Would sulphur and salt do any good? I am of the opinion that the rust forms in or under the ground around the roots. Is the rust an insect or a fungus growth? I claim an insect, for I have seen it under a strong glass; others have argued to me it is of fungus growth. The wind spreads the dust and forms on other plants; it has affected the asparagus very much within a few miles of Philadelphia. The prices are good, but with bad weather and blight we do not cut more than half a crop. Would sulphur sprayed on the plants do good or injury?

ANS.—We doubt the value of sulphur. Dr. Halsted, of New Jersey, tried spraying with solutions of glue, gelatin, lime, soap and also milk. The Palmetto variety is less susceptible than some other varieties, because of its thick skin and downy covering. The object of this spraying was to give the plants an artificial coating. These experiments were on a small scale, but the results indicate that this plan of coating the plant is useful. The plants sprayed with soap and with milk were very free from rust, and so were those sprayed with gelatin. You ought to send to the New Jersey Station (New Brunswick) and the Geneva (N. Y.) Station for bulletins on this disease. Bulletin 188 from Geneva shows that the rust is a fungus or parasitic plant which grows within the asparagus and absorbs the juices which should go to build up its tissues. Bordeaux Mixture has been used for spraying the plants, and it seems to be successful where it can be put on all parts—thoroughly. On Long Island a large machine costing over $200 is used for this purpose, and it does its work well. Spraying with small pumps and single nozzles does not give satisfaction.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

Write for our WINDMILL BOOK

The man who knows most about windmills has written a book. It is a 40-page book with more than 100 pictures. To the man who wants a windmill every page of the book is interesting. Not a word will he skip. And when he is done he will know all that anybody knows about windmills and what they should do. He cannot be fooled; but the man who buys a windmill without reading this book will regret it. Simply send us your address and the book will be mailed to you free.

The writer of this book is president of the Aermotor Company.

But the book is not biased, nor unfair. It is a book of information, written by the man who knows more than any other man about windmills.

We are not trying to sell you direct. We simply want to tell you the facts that may save you a costly mistake.

Half the cost of your outfit is in putting up and taking down. You can't get that back if you make a mistake.

When you know the facts, get the windmill you want; and if you decide on an Aermotor, you can go to your dealer for it. We will give you the name of agent nearest to you.

The writer of this book started in twelve years ago to make Aermotors. The field was overcrowded. Makers with millions of capital, and tens of thousands of agents controlled all the trade there was.

The Aermotor Company had little capital no trade, no agents, no reputation. 'Twas a pigmy among giants.

That was twelve years ago. Today the whole earth is dotted with Aermotors, and more Aermotors are sold than of all other windmills put together.

That is a record with scarcely a parallel in the history of invention. The book will tell you how it was done.

5,000 experiments were made before the first Aermotor was built. Sixty-five windwheels were tried before the right one was found.

He tells you how he knew that was right. He shows you why Aermotors work in the lightest breeze, when all other windmills stand still.

He kept on improving until 55 patents had been issued on Aermotors, covering 55 important features no other windmill has.

The book will tell you about them, and about the steel towers which he first made when other makers deemed them impossible.

In twelve years he has cut the cost of wind power to one-sixth what it was when he started.

Think what that means to you.

He has invented machinery to make each part of the Aermotor at the least possible cost.

More than half the world's windmills are now made in this factory; made by perfect machinery, in such quantities and so cheaply, that Aermotors cost far less than any other windmill worth having.

No man who reads this book will buy any windmill but the Aermotor. He will know why the majority buy Aermotors and he will demand what they seek. He will not be content to pay more than our prices for a windmill half so good.

That is why we issue the book, of course. But it is better for you than for us. It saves you all you would waste if you bought the wrong windmill. It gives you the knowledge you need to avoid a costly mistake.

Write a postal for the book.

AERMOTOR CO., 1206 TWELFTH STREET, CHICAGO

We have another book about Power Aermotors for doing all sorts of work—for grinding, for sawing, for cutting feed, shelling corn and running many kinds of machinery. This book is free, too. Also a book about Pumps, Tanks, Substructures, Pipes, Fittings and all sorts of Water Supply Goods. We make 160 Tons of Piping daily. Our plant occupies more than 30 Acres. This is considered a pretty good sized farm in New England.

Cracking the Butter Bowl.

A. L. D., Southampton, N. Y.—Will someone tell me how to prevent a new butter bowl from cracking? Every one I purchase cracks, so that it is useless in a very short time.

ANS.—Do not let the bowl entirely dry out. Keep it sweet and clean by steaming or thorough scalding, rather than by much sunlight. Wooden trays, or shallow tubs, can be used instead of the butter-bowl, and are just as cheap and easy to handle. J. A. F.

The Slaughter of Tame Pigeons.

E. P. R., Ohio.—You are too severe in criticising hunters and trap-shooters. You are prejudiced. No one but a strict vegetarian can consistently condemn those who shoot or fish. Of course, at first glance, to deprive a bird or animal of life for *sport* seems cruel. But every one who eats meat or fish kills, or by buying encourages another in killing for their *enjoyment.* The hunter or angler has double reason for his course, as he enjoys both the killing and eating of his game and fish. Many as tender-hearted, gentle, men and women as ever lived are fond of hunting and fishing. They are great nature-lovers always. Our late Presidents, Harrison and Cleveland, and, I believe, McKinley also, were and are lovers of shooting and fishing. The Presbyterian and Methodist ministers in my town are ardent lovers of quail shooting. Many ministers are fond of angling. Even the Founder of Christianity "went a fishing," and it was not necessary, for He proved He could create at will as many loaves and fishes as were needed. If it were not for hunters no farming could be done in this country. Bear, deer, wolves and other animals would still be numerous. Even now, if hunting were prohibited for 10 years, rabbits would be a serious menace. One pair breeding five times each Summer, with eight at a litter, making no allowance for accidents would amount in six years to over 250,000,000. One pair of quail multiply as follows counting on an increase of 18 young to each pair per year: End of first year, 20; second, 200; third, 2,000; fourth, 20,000; fifth, 200,000; sixth, 2,000,000; seventh, 20,000,000; eighth, 200,000,000; ninth, 2,000,000,000; tenth, 20,000,000,000.

ANS.—It was not the intention in the editorial referred to to condemn all hunting and fishing; but to show that, as some of these shooting matches are conducted, the effect must be most brutalizing on all who witness or take part in them. We do our share of hunting and fishing as opportunity offers. The wild birds and animals in woodlands which hunters go over thoroughly every year, come to maturity, if they do at all, because of their watchfulness in keeping out of the hunter's way. They have a constant training in looking out for for themselves; but how different it is with the tame pigeons or rabbits! Until let loose to be destroyed, they have been cared for by man, and have not had, like the wild ones, to hustle and scratch to save their lives. What reason have they to fear man as their enemy? All at once this is changed. They are let loose, frightened, and men taking advantage of their helplessness, murder them. If this is sport, then we have not understood the meaning of the word. It looks like treachery of the most brutal stamp, scarcely equaled in savage warfare. There may be sport in hunting the wolf, bear, wildcat or wild turkey, which can get out of the way or defend themselves if cornered, but it would look inconsistent to take this as an excuse for shooting faithful Towser, the house cat, the Jersey cow or the old gobbler for mere sport. Life may not be any sweeter to those domesticated animals than to the wild ones; but should it not be considered that we have taken them under our care, and thus removed from them the wild instinct given by the Creator as a protection, that they might have an equal chance for life with other beings? Man was made to have dominion over all things. The fish, flesh and fowl are for his use, but it does not follow that he should misuse his powers or inflict needless cruelty on any of his subjects. We acknowledge the good work of the hunter and butcher in providing food for us, and preventing the animal population from crowding us out. What we wish to protest against is the degrading brutality shown in some shooting matches, and no doubt E. P. R. holds the same opinion in regard to this phase of the matter.

The Care of an Incubator.

H. S. R., Youngstown, O.—Too many of my chicks die in the shell in the incubator. Could you give me any information to remedy it? We hatch in the cellar, a dry cellar, but always have plenty of moisture in the incubator; have the two-inch ventilators in top of machine about one-half inch apart, and run it steady at 103 degrees. My old chickens are all healthy but somewhat fat. What can I do? The egg shell seems to be tough.

ANS.—Incubators, when running, need a great deal of sweet, fresh air, as it makes the chicks strong, with plenty of kick in them which the poor little things need for their final struggle. The room where they are should be well ventilated twice a day. The air becomes heavy very quickly where a kerosene oil lamp is burning, and the embryo chicks rapidly lose vitality when breathing it. They also need generous airing out. After the first week the egg chamber doors should be left open about five minutes at first, and the time gradually increased, but never allowing the temperature to fall below 90 degrees. The cellar, if well ventilated, and the air fresh and sweet, is a good place for them; as the temperature is more even, and so they need less attention. The valves on top of your machine sound as if your rig may be the Cyphers. This one has, I think, the best ventilating and temperature regulation of any machine on the market, but the valves should be kept closed during the hatch, unless your atmosphere is especially humid. You speak of plenty of moisture in the machine. Most manufacturers of incubators now advise running them dry till they are shut down on the eighteenth day, when either moisture is applied through sprinkling the floor of the room, pans of water set around on shelves, or the vessels supplied for that purpose in the egg chamber filled. I fill my Prairie State pans about half full when I shut down, and I sprinkle the floor about the Cyphers and keep the atmosphere of the room damp from the time the eggs pip till the hatch is finished. The chicks slip out easy and are all right.. The eggs at first contain enough water in themselves till just at the finish, and even then it must be applied judiciously, else the birds will be drowned while in the shell, but a tough skin indicates dryness at the finish, and mature dead birds low vitality and wrong or insufficient ventilation. Each locality where an incubator is run appears to have its own peculiar atmospheric conditions, and the operator has to expend lots of patience and perseverance in solving the problem of handling his rig to get the best possible results. With the most painstaking efforts it is very difficult for outsiders to give efficient advice. It's something like Heaven—each of us has to work out our own salvation "with fear and trembling."

FRANCES ELLEN WHEELER.

When and How to Thin Peaches.

J. H. R., Stuarts Draft, Va.—I was to commence thinning peaches to-day. My neighbor told me I should wait awhile to see how many would drop off. They are as large as marbles and the trees are very thrifty; first crop. I can do it better now than later on account of my work. What is your advice?

ANS.—Peaches should be thinned about when they are the size of full grown peach seeds, and not before. Later than that is said to be better than earlier, by those who have done the work very extensively. The tree naturally often casts considerable of the fruit, and there is thought by some to be more safety in waiting until after this natural drop before thinning, but we have held to the belief that there is not likely to be much dropping if the fruit is not too thick. There is more danger of leaving on too much than too little, so everyone finds upon trial. Mr. Morrill, of Michigan, thins his peaches 10 inches apart, and Mr. Hall, of Connecticut and Georgia, has changed from six inches to eight. The first thing to do in thinning is to shake the tree quite hard, which will cause much of the defective fruit to fall; then thin unmercifully. It pays better to grow fruit than seed on a fruit tree.

Ruralisms

NOTES FROM THE RURAL GROUNDS.

STOCKS FOR GRAFTING ROSES.—Something of a controversy is now going on in the horticultural trade journals concerning the best stocks for rose grafting. Jackson Dawson, of the Arnold Arboretum, Boston, who has had much experience in propagating hardy roses, warmly recommends Rosa multiflora, a Chinese species, for the purpose, but most growers are still wedded to the Manetti, a strong growing form of the hybrid China rose found growing wild in Italy nearly 50 years ago. Manetti is the stock almost exclusively used for the imported roses so freely offered in all large cities. It is not at all adapted to our climate, as it makes a great mass of fibrous roots near the surface, subjecting the plant to severe checks from dry weather and to premature ripening in the Fall. There is also a tendency to throw up suckers unless the union of the bud or graft with the stock is very deeply planted. Thousands of purchasers of these tempting grafted roses are soon grieved to find their once thrifty roses replaced by worthless briers, as the Manetti sprout soon monopolizes the whole vitality of the plant. This characteristic is less objectionable when used for grafting forcing roses, as they are grown under such a system of constant inspection that suckers can never make much progress. We have tried many substitutes for Manetti on the Rural Grounds and find the Michigan or Prairie rose (Rosa setigera), R. Wichuraiana and the sweetbriar, R. rubiginosa, have given us good satisfaction where perfect hardiness is required, though certain hybrids of sweetbrier and Wichuraiana are still better. All make good deep roots, and are little affected by dry weather when established, and are not at all disposed to sucker. The best of all stocks in the Rural experience is produced by crossing Crimson Rambler with Clothilde Soupert, both varieties of R. multiflora. Some of the crosses are almost thornless, and of extraordinary vigor in growth. A three-year plant in ordinary soil cut back yearly has developed a woody base nearly three inches through. There is no inclination to throw up sprouts, and for all budding purposes this stock works with great ease. In hardiness it seems little inferior to the native species. For grafting purposes we do not care to use the stems, as sections of the larger roots of any of the species mentioned may be grafted with the ordinary splice graft, as it is not always easy to make a tongue in rose wood on account of the pith. The grafted roots may be well wrapped with waxed cloth like an apple graft, packed in damp moss or old sawdust and kept in a warm place for two or three weeks, after which they should be potted up in small pots and placed on a bench under glass to grow. If the grafting has been carefully managed they will soon make fine plants. For tree rose effects we much prefer to bud high up on strong hybrid sweetbrier shoots, and trim off all other shoots and branches from the stock as soon as the bud has formed a fair top.

The whole question of propagating roses by budding and grafting is still undeveloped in America, though the propagation by cuttings is carried on to greater perfection than abroad, resulting in cheaper plants of most varieties than can be procured elsewhere. While most tender and everblooming roses thrive best on their own roots, some of the finest hardy varieties root with difficulty or make only feeble plants when induced to grow. It is important to find strong-growing stocks suited to our climate for such roses, that we may not be deprived of their beauty and fragrance, and it seems that they are most likely to be produced by hybridizing and breeding. The grape industry of France is being rehabilitated after threatened destruction by Phylloxera by grafting the native vines on American stocks, mostly of hybrid origin, and stocks are being bred for special purposes, such as avoiding chlorosis, a disease caused by a great excess of lime in the soil. Hybrid stocks may be absolutely sterile in themselves, but prove of great value for grafting on account of extraordinary vigor or special adaptation for some important purpose.

A BEAUTIFUL HARDY GRASS.—Reference was made on page 818, volume for 1900, to the value of stems of Eulalia gracillima univittata, now considered as a variety of Miscanthus Sinensis, for Winter protection of shrubby plants. Nothing we have used has given so much satisfaction for mulching or tying up. The leafy stems are light but rigid, and afford good protection, without interfering with the necessary ventilation. We think so highly of it that a privet hedge has been thrown out to make place for it. This Eulalia makes a beautiful Summer hedge or dividing line, but has been little used for this purpose, and while the tall brown feathery tufts are not attractive in Winter they form effective wind-breaks. Fig. 171, page 418, from a cut kindly furnished by Bobbink & Atkins, Rutherford, N. J., shows what can be accomplished by planting it in beds or groups. The edging of this group is evidently made up of Day lilies or Funkias. Repeated trials have shown that cattle and horses eat the growing stems of the Eulalias with relish, and in view of the enormous quantity of forage a small planting would give, it may be worth while to test the different varieties for the purpose. Young plants or divisions may be had for about $5 per 1,000, and if set about two feet by three in good soil a permanent and exceedingly productive green forage planting would be secured. After the second year it may be cut repeatedly without injury, but the feeding value remains to be determined. It is always well to burn over the old tufts every Spring, as the new growth starts more evenly and vigorously than when compelled to push up through the stubble. It has lately been determined that Miscanthus has precedence over Eulalia as the generic name of these beautiful hardy grasses, but we may consider the latter as popularly adopted, and likely to remain in use by most gardeners. The striped variety known as E. Japonica variegata and E. Japonica zebrina are handsome in their way, but much too coarse to be used extensively except for backgrounds.

A GOOD METAL POT.—Early in April last year the Rural Grounds received from S. R. Divine, Loch Sheldrake, N. Y., two dozen metal pots as a substitute for the earthen pots so universally used for growing plants. They were of the standard four-inch size, differing only in having a much larger drainage hole in the bottom than the usual kind. They were of galvanized iron, and had been dipped after being pressed into shape out of a single piece of sheet iron. The drainage hole, being nearly two inches in diameter, must be closed with a piece of sod or other porous material to keep the soil in. Metal pots have always been condemned, as it was thought that porous sides were necessary for successful plant growth, but the thousands of healthy plants in tin cans in window gardens all over the country sufficiently disprove this opinion. We planted melons and cucumbers in these pots, using sods for drainage cover, at the same time planting similar seeds in earthen pots of the same size. When turned out in the field seven weeks later no difference in size or strength of the plants could be noticed, and both lots grew equally well throughout the season. The metal pots nest together very closely and only weigh about one-third as much as the earthen kind, and have the additional advantage of not breaking when dropped, although they can be bent by strong pressure. These sample pots are very well made, and after a year's exposure to weather are as bright as at first. They look as though they would endure many seasons' usage. Mr. Divine says his locality is so cool that it is necessary to start all early melons, beans, sweet corn, etc., in pots under protection to avoid late frosts. He finds these pots, which he has been perfecting for some time, just the thing, as thousands may be handled and stored with little trouble and expenditure of space. We understand that they cannot yet be manufactured at prices to compete with common pots, but he thinks that when their durability and ease of handling is taken into consideration they will in the end prove the cheaper. A season's experience seems to prove the truth of this assertion. W. V. F.

The Worden-Seckel Fear.

In your issue of April 20, some one, in answering H. G. H., of Cadiz, O., says the Worden-Seckel pear originated in Canada. I had always supposed this variety originated with the late Schuyler Worden, Minnetto, N. Y., the father of the famous Worden grape. I wonder if I am mistaken; if so, shall be glad to be set right. H. S. W.
Cayuga, N. Y.

In my reply of April 20 to a former question about the Worden-Seckel pear I did make a mistake about the origin of that variety, as I find from a consultation with one who was personally acquainted with the originator and his work. H. S. W. is correct in his belief, for the seed from which the original tree was grown was taken from a Seckel pear and planted by Schuyler Worden at Minnetto, N. Y., about 1860. The locality is on the west side of Oswego River, and in a good section for growing pears. It is a variety well worthy of being planted by all lovers of good pears, for it is larger and much more handsome than its parent, and as good in quality, which is equal to the best of all pears. My opinion is, that the simple name Worden is sufficient and that it should be so listed by the authorities in pomology and in the catalogues of nurserymen, and be so used by the public in general. H. E. VAN DEMAN.

Hope Farm Notes

WATER WORKS.—That title will fit all work at Hope Farm. It is still wet as a sponge. Rain has fallen more or less every day for the past 11 days. During these 264 hours there may have been 15 hours when evaporation beat precipitation. We saw the sun about three hours on Decoration Day, and the day following tried hard to entice the prodigal sun back to his business. He began work, but in less than an hour a cloud arose and spilled twice as much water on us as the sun pulled out. While that hour was only one-tenth of one per cent of the duration of Noah's deluge, it seemed as though nearly 15 per cent of his total rain fell! Well, we are not "kicking!" We are like Julia, tied up so we can't do anything. Unlike her we might sour the milk of human kindness as circumstances force it out of us, but that would be nonsense. The wise men tell us that the trouble with this weather is the fact that "an area of rain and fog" hangs over the eastern part of the country. There is not energy enough in the air west of it to blow it off into the ocean! It's a great satisfaction to know about these things, but that sort of knowledge doesn't plant corn. We Jerseymen want to know what ails the western people that they can't raise a little more "energy!" This makes me think that men sometimes feel clouds of depression settle down over them until their wives or some one else starts a little "energy" with the tongue, and off rolls the cloud.

FARM PROSPECTS.—Up to June 5 we had not planted a hill of field corn. A small patch of early sweet corn is up, but our corn ground is so hard and moist that we could not plow it properly. I won't plow that ground so it turns up thick and full of clods if I have to wait until the Fourth of July! Some farmers have corn well up, but it is pale in color, and the soil is sticky and full of clods. I think it was plowed too early, and that crops will suffer for several years in consequence. I expected by this time to have at least 12 acres of corn up. It is a sorry outlook for corn! . . . The oats are very fine. The young clover and Orchard grass have "caught" well—in fact, all grass and grain are very promising. We made the mistake of sowing rye and Crimson clover together last Fall. We cut and fed to the stock as long as the rye was tender, and then, rather than lose the clover, cut all with the mower. It is impossible to cure it in this weather, so we hauled several loads to the barn and scattered the green stuff all over the mows. It will make fair feed for the horses and save hay, but the cows will only pick out the clover. . . . We have nearly five acres of potatoes planted. The rain beat us on the rest. We got them in about right—taking time to fit the ground well. I was afraid of this wet, so we used large seed pieces well dusted with sulphur. They have made nearly a perfect stand thus far. In some of the farms near us where small seed pieces were planted very early nearly one-third have failed to sprout. We planted in hills this year, making deep furrows one way and light marks the other. Part of them were covered by running the Acme crosswise of the furrows—others with the cultivator run lengthwise. In this wet season the latter plan seems best. . . . I see some farmers out in the damp weather and wet soil cultivating such crops as have come up. It seems to me that they do more harm than good by such work. The soil is water-logged now. Working the surface will only prevent evaporation. Horse and man pack and paste the mud down into clods. No weeds are destroyed without sunshine—they are only transplanted! A light plow would do better work, but I would keep entirely out of the field.

HOME NOTES.—Our ice has caught the prevailing depression, and is easily moved to tears. Most of the small ice houses all about us are failing this year. Our house was made out of an old hen-house. The ice may last until September, but I doubt it. In case of doubt I believe in action, so we purpose to get some of the benefit of that ice before it all goes. It makes a very nice jacket to go aronnd some of Julia's cream. The Hope Farm family can raise the temperature of their idea as to the value of living several degrees over a can of ice cream. No cornstarch in ours, please—just the pure cream and fruit! What's the use in talking about pie when this combination of cow and ice house can be found on the farm? I have known men who kept 25 cows or more and received less than two cents a quart for milk, to growl like bears if their wives wanted a little cream for home use. What ails such men? I wish their wives would give an opinion! The farmer ought to live on the fat of the land—that is, unless he begins to find it hard to button his last year's vest. In that case he should give his share to the lean members of his family. . . . After waiting a week for a clear day Grandmother came home from the hospital between showers. We had the front room downstairs all ready for her with a wood fire burning in the grate. She was glad enough to get back to Hope Farm. Scrambled eggs were good enough for the rest of us that night, but Grandmother had a squab on toast. We must push some of the little chicks into broilers! Our scales show that Grandmother lost 13½ pounds while in the hospital. Most of us who find our flesh becoming a nuisance would lose it by some other method of pruning if we had our own way. The little girls especially were glad to have Grandmother back. It was pleasant to see the three again sitting together over their sewing.

COW CHARACTER.—I have the following note from a friend in Maine:

I was surprised to read in the Hope Farm Notes of the kicking cow Julia; did not know that any up-to-date farmer had such a cow. I am not strictly up to date myself, but have raised and kept a good many cows, and never had a kicker. If I had a hired man who should discover a kicking cow in my herd I would let him go into some other business, where his talents would be more likely to be appreciated.

H. B. W.

I agree with that. If I should raise a heifer that became a confirmed kicker I should certainly blame myself rather than the cow. We did not raise Julia. I bought her as a four-year-old. She was nearly dry when I looked her over and she did not kick. I didn't like the appearance of her eye, but her other "points" all indicated rich milk, and I risked her eye. The man who sold her must have forgotten her disposition. That is a charitable way of considering him. This cow is naturally ugly. She will fight the other cattle, chase the children, pull down fences and plan like a politician to get what doesn't belong to her. If I ever raise a "kicker" I shall hold myself responsible for her, but Julia is not a Hope Farm product. All we can hope to do is to make her walk a straighter line. We have her daughter with her first calf—as mild and gentle as need be. Another letter that makes me thoughtful is the following:

In your paper dated May 18, page 359, in Hope Farm Notes, I notice the following in reference to richness of milk: "This milk is so good that a gallon of it represents a pound of butter." Your milk being very rich a gallon would not weigh more than eight pounds. This would be equal to about 12 per cent butter fat for 100 pounds of milk. Milk as rich in butter fat as this could be sold in Lancaster, Pa., for 12 cents per quart. I would like to know what strain of cows you secure your milk from. We have a fairly good herd of registered Jersey cows, and they average a pound of butter from 16 pounds of milk.

I thought I made that plain. I said that a gallon of Julia's milk brings money enough to buy a pound of butter made by some man back farther from market. I was afraid, after I wrote it, that some one would get things mixed up. No! No! I do not intend to offer Julia as a famous butter cow. She is a good cow—though probably not so good as those owned by our friend. Her bad habits condemn her, and she will end her days this Fall in a butcher's shop. Her kicking is not patriotic, and unworthy of going down to posterity.

USES OF ADVERSITY.—As I write the clouds gather again and the fog spills down. "Looks as though we might have rain!" The best thing I can do, under the circumstances, is to quote from a letter just at hand from a good friend in California. He puts it better than I can:

I cannot help feeling that the unfavorable seasons, pests, disasters and other unfavorable conditions that we see about us, are for the purpose principally of calling the attention of weak mankind to the fact that there is an over-ruling Power in the universe who knows His business and what is best for man much better than man does himself. For instance, I cannot now see why we should have so much rain at this season, when perhaps three-fourths of the hay in the country is unprotected, and large quantities have been spoiled. It is true that these rains lay the dust and freshen the air, and benefit all trees and growing crops to some extent, but the man whose entire crop is hay cannot or does not feel happy about it. Must we not after all conclude that every man receives just what is best for him in order that he may develop towards perfection and strengthen the individuality that God has given him, or else admit that we are the victims of chance, and that God's plans are not perfect in all their details? H. G. K.

Amen! says the Hope Farm man. The great Manager of the universe knows more about this season than I do. You are right—the only man who is worth counting is he who goes through fire and has the trash burned out of him. Wu Ting-fang, the Chinese Minister, spoke at Grant's tomb on Decoration Day and among other things said:

Twenty-three centuries ago, Mencius, who next to Confucius was the greatest philosopher that has ever flourished in China said: "When Heaven is about to confer a great office on any man, it first exercises his mind with suffering, and his sinews and bones with toil. It exposes his body to hunger, and subjects him to bodily privation. It confounds his undertakings. By all these methods, it hardens his nature and supplies his incompetencies."

It would hardly be appropriate to say "Amen" in referring to a Chinese "sermon," but that strikes me as bed-rock truth—I don't care who said it. Brace up against trials and misfit conditions, and in time one comes to have the power of a giant. Fall down before them and they will roll over you and flatten you like a pancake. Mencius referred to a man who is to hold an "office." I consider that the head of a big farm family occupies one of the noblest offices within the reach of human endeavor. H. W. C.

WHEN you write advertisers mention THE R. N.-Y. and you will get a quick reply and "a square deal." See our guarantee 8th page.

KILLED-DEAD.

You know that the horse buyer knocks off $50 or more for every lump or blemish on a horse. Get full value for your horse—don't have any lumps. Cure him with

Tuttle's Elixir.

It is guaranteed under a forfeit of $100. to cure any case of *horse ail, curb, splints, contracted cord, callouses, thrush, etc.*

Used and Endorsed by Adams Express Company.

TUTTLE'S FAMILY ELIXIR cures rheumatism, sprains, bruises, etc., Kills pain instantly. Our 100-page book, "Veterinary Experience" FREE.

Dr. S. A. TUTTLE, 30 Beverly St., Boston, Mass.

Beware of so-called Elixirs—none genuine but Tuttle's. Avoid all blisters, they offer only temporary relief if any.

ONCE IN A LIFE TIME

is often enough to do some things. It is often enough to buy a wagon if you buy the right kind. The

ELECTRIC HANDY WAGON

lasts that long under ordinary conditions. First the life of a wagon depends upon the wheels. This one is equipped with our Electric Steel Wheels, with straight or stagger spokes and wide tires. Wheels any height from 24 to 60 inches. It lasts because tires can't get loose, no re-setting, hubs can't crack or spokes become loose, felloes can't rot, swell or dry out. Angle steel hounds.

THOUSANDS NOW IN DAILY USE.

Don't buy a wagon until you get our free book, "Farm Savings."

ELECTRIC WHEEL CO., Box 88 Quincy, Ills.

STUDEBAKER QUALITY

Ask Your Neighbor,

who owns one, if his

Studebaker Wagon

has not given him the most perfect satisfaction through all the years in which he has used it. That is the experience of multiplied thousands of their users and it will be your experience if you buy one. Ours is the only large wagon works in America that is still managed by the founders as it has been since 1852. Nobody else has had so many years of experience in wagon making art and consequently no other wagon is so good. Ask your dealer for the Studebaker Wagon. If not there, write us direct and we will tell you where you can get them.

Studebaker Bros. Mfg. Co., South Bend, Ind., U.S.A.

BUGGIES AND HARNESS

HARNESS $4.15

THIS $50 TOP BUGGY $28.50

YOU CAN BUY FROM US AT FACTORY PRICES

BUGGIES, PHAETONS, SURREYS, WAGONS, ALL KINDS OF HARNESS. We will sell direct to you a vehicle or harness as cheap as dealers buy their goods in car-load lots. Don't pay profits to middlemen. Our work is all high-grade, correct style, and elegantly finished.

SEND FOR FREE CATALOGUE SHOWING LARGEST LINE VEHICLES AND HARNESS IN THE UNITED STATES.

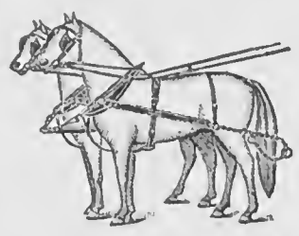
All Work Guaranteed and Shipped on Approval.

CONSUMERS CARRIAGE & MFG. CO.,

232 So. Desplaines Street, CHICAGO, ILL.

No. 5034, Concord Spring Buggy. Price $60.00.

No. 2016 Canopy Top Carriage. Price $98



No. 602 Team Harness. Price $18.90.

No. 3034 Buggy. Price $38.30, with leather quarter top.

Buy Your Carriages Where They Are Made

You can save two profits by buying your carriages, buggies, phaetons, surreys, wagons or harness right from our factory. We are **manufacturers** of vehicles and harness, and are absolutely responsible for every article that leaves our place. You not only have an absolute guarantee of protection, but you make

A Great Saving

It is an actual fact that you can purchase a vehicle or harness from us for 25 to 35 per cent less than you can get the same value elsewhere. **We sell at wholesale prices,** have no agents or salesmen to pay. You get the benefit of all this saving as well as the dealer's profit.

With every purchase is a written guarantee that if the goods we send you are not satisfactory, you can return them. We will pay freight charges both ways. Send for manufacturers' catalogue and see for yourself. It costs you nothing.

THE COLUMBUS CARRIAGE AND HARNESS COMPANY, Box 772, Columbus, Ohio.

SUBSCRIPTION: ONE DOLLAR A YEAR.

To foreign countries in the Universal Postal Union, $2.04, equal to 8s. 6d., or 8½ marks, or 10½ francs.

"A SQUARE DEAL."

We believe that every advertisement in this paper is backed by a responsible person. But to make doubly sure we will make good any loss to paid subscribers sustained by trusting any deliberate swindler advertising in our columns, and any such swindler will be publicly exposed. W protect subscribers against rogues, but we do not guarantee to adjust trifling differences between subscribers and honest, responsible advertisers. Neither will we be responsible for the debts of honest bankrupts sanctioned by the courts. Notice of the complaint must be sent us within one month of the time of the transaction, and you must have mentioned THE RURAL NEW-YORKER when writing the advertiser.

Name and address of sender, and what the remittance is for, should appear in every letter.
Remittances may be made in money order, express order, personal check or bank draft.

THE RURAL NEW-YORKER,
409 Pearl Street, New York.

SATURDAY, JUNE 15, 1901.

REPORTS from some sections are that in spite of a heavy bloom on the apple trees comparatively little fruit has set. The drenching rains during flowering are responsible for this loss. It remains to be seen how general this condition is. In ordinary years a crop estimate made during blooming will give a fair indication as to the crop. This year all such estimates must be revised. We want to hear from readers everywhere about this matter. What are the fruit indications *now*? What proportion of the fruit has actually started? Has spraying been as effective as usual? Now gentlemen, get together on these things!

*

WE are afraid there is trouble ahead for a good many of us. The season so far has been very wet and most farmers are two or three weeks behind. Much land that has been planted has been improperly fitted, plowed, harrowed and planted when too wet. Some have plowed, harrowed and planted almost in mud. Many seeds have rotted; some whole fields of potatoes gone. The land has been fined, as it was too wet to harrow, and the harrow has done more harm than good. The soil is lumpy, and the horses going over fields have simply scratched about an inch on top, while they stamped all under so hard that nothing can easily penetrate the soil. Weeds will be thick, and as haying and hoeing will surely come together, something will be neglected, and we look for poor yields on many farms.

*

DANISH butter enjoys a high reputation in European markets, and it is evident that the dairymen of Denmark intend to keep in advance of the procession. A number of them have formed an association for the employment and maintenance of an expert, who will visit the farms of the members at certain intervals to ascertain the quality and quantity of milk from each cow, and to keep an accurate record of the same. The results will be summed up at stated intervals, and a reliable statement given as to the value of the cows. It is not, however, necessary for a farmer to join an association to carry out such intelligent work; each one may and should carry out these estimates for himself. The interesting point, however, is that Danish farmers are so fully alive to their best interests, and so ready to work together to hold trade. The fact that they have almost a monopoly of markets we are trying to reach makes any study of their methods valuable.

*

A CORRESPONDENT is inclined to criticise the attitude of THE R. N.-Y. on pigeon-shooting and similar brutal sports, claiming that it is no worse than hunting or fishing, which are generally conceded to be legitimate and not inherently cruel pastimes. The hunting of wild game in a sportsmanlike way is vastly different from the deliberate public slaughter of tame doves, with the incidental agony of painful wounds that do not cause instant death. Yet we think that the time has arrived in the progress of real civilization when even the pursuit of wild creatures purely for recreation in populated districts should cease. Game birds and animals really have little chance against the modern battery of dog and perfected gun, and with the exception of a few destructive species they may well be preserved as the friends and companions of man. It should never be forgotten that humanity has as yet barely emerged from barbarism. We all feel a recurring desire to go out and kill something, or at least overreach somebody in one of the many devious ways of legal robbery which constitutes modern business. It is well to restrain these savage longings as much as possible. While progress is slow toward human refinement, nevertheless real advancement is taking place. One of the hopeful opportunities for substitution of artistic interest for cruelty is the pursuit of wild creatures with the camera instead of the gun. Accurate and vivid photographs of birds and animals have been caught in their natural surroundings by skillful and patient amateurs. To secure such pictures requires the exercise of the highest ingenuity of woodcraft, and is a pastime worthy of the most ardent lover of nature. To capture a successful portrait of a wary denizen of the field or forest is a satisfaction that far transcends the brutal exercise of the slaughtering power, and does the timid subject no harm.

*

THE proprietors of transportation companies were quick to see the advantage in their controlling grain elevators and other storage facilities. They were thus able to handle the grain, and could practically freeze out those who tried to put up elevators along their lines. While much of the profit thus made is legitimate, and merely the result of business methods which looked into the future and studied the possible relations between carrier and the produce carried, yet there is no doubt that in numerous cases they have taken an unfair advantage of the grain farmer, who was obliged to depend upon their storage and suffer from their manipulation of prices. In some sections of the West farmers are forming associations and putting up elevators of their own in which they can hold grain independently of the railroads. They have no quarrel with the latter, but are simply meeting business methods with business methods, and this seems much nearer to common sense than any attempt to pose as martyrs, or urge the enactment of laws prohibiting carriers from engaging in any outside business.

*

THIS is an era of giving. Hardly a week passes without the report of some wealthy man who has given millions to the cause of education—in fitting out schools or libraries. It is one thing to gather a fortune and then give it away, but quite another to give it away without gathering it. Those who do this are seldom mentioned. One such man is Prof. S. M. Babcock, of Wisconsin. It is safe to say that his invention of the milk test bearing his name revolutionized the dairy industry of this country. The Wisconsin Legislature presented him with a bronze medal, and in the course of his remarks Gov. La Follette said:

> A colossal fortune was within his easy grasp. He put it aside and gave to the public the priceless product of his genius and disinterested labor. In the midst of the commercial spirit in which we live, surrounded by the sordid desire for wealth; its unscrupulous methods of attainment, idolatrous worship, its unworthy power, we have in this act an example of pure-minded, honorable conduct, placing a public benefactor high in the confidence of the people, above all suspicion of taint. And this dedication of his invention to the public possesses even a greater moral than money value.

The rich men who give their millions do well, but they would do better if they gave less accumulated money and more scattered opportunity. The world would be better off in the end if the rich and shrewd would improve conditions, so that poor and middle class would need less of their money!

*

FOR centuries mankind has endured the mosquito—not willingly, but because there seemed no help for it. This little pest has made human life a burden, and has also been the means of spreading malaria, yellow fever and probably other diseases. We failed to fight the mosquito successfully because the warfare was conducted against single adults. They were screened out of the house with partial success, and now and then one was caught in his bloody act and killed. This process proved about as effective as the plan of emptying the ocean with a tablespoon. Now the fight against this pest has been changed from individual combat to wholesale slaughter. The scientific men have shown us how to destroy the baby mosquitoes. Their quiet study of its habits has been more effective than all the groans, slaps and bad language which the practical men have indulged in. The insects breed in still, fresh water. They will not breed in running streams or in salt water. If all the little pools and stagnant ponds in a neighborhood can be drained the mosquito crop will surely fail from drought. Where this drainage is impossible a thin film of kerosene oil over the surface of the water will put an end to the "wigglers." Of course this plan requires the coöperation of neighbors in order to make it effective—for that matter so does every effort against pests which injure us, be they mosquitoes or men. By taking care of all water holes or stagnant places on our own premises we may do much good, but this work of fighting mosquitoes is a public service in which all should take a hand. The so-called "board of health" to be found in most communities might just as well enforce sanitary laws against the mosquito as to quarantine patients who suffer from contagious diseases. It is reported that the city of Winchester, Va., has been made nearly "mosquito proof" by the enforcement of an ordinance requiring people to use kerosene in all vaults and sinks. Formerly the insects were so bad that guests were driven away. On Long Island an area containing 25 square miles has been examined by an engineer and every stagnant pool or pond will be drained or oiled. These things show that people are moving against the mosquito, and it is high time they did so. Science shows how the work may be done, and now provides a motive for doing it by proving that this winged and spurred enemy is responsible for spreading disease.

*

WE know of a farmer who was started into better farming by the questions of a little child. He was a good-natured, easy-going man whose great fault was a lack of system and purpose. At times he would wander aimlessly about doing a job here and another there, without thought or careful planning. His little child tagged him about with one simple question: "Father, what are you going to do next?" She saw her father turning from one thing to another, doing nothing thoroughly—making so many turns and changes that her little mind was confused. "Father, what are you going to do next?" This question was asked again and again. At first it annoyed the man, but he was naturally good natured, and the child was so persistent that at last the man fell to asking himself the same question. He began to see the folly of talking about "the next" thing before the thing in hand was done. He also saw the loss that was sure to occur in taking up the next thing before it was well thought out. This little tale is true. The farmer was driven by his child to ask himself the same question, and in time he was able partly to organize his plans, and make the connection between the present job and the next one more businesslike. What are *you* going to do next?

*

BREVITIES.

Of all the flowers from roses down to tansy
There's nothing hits me like unto the pansy.
Them little posies—jest like people's faces—
Keep noddin' to ye in their proper places.
Proud, patient, smilin', happy, sweet an' sour,
Why, I can sit an' watch 'em by the hour,
An' note their changes; when the sky is bright,
They jest beam out with cheerfulness and light;
But let a cloud come skipping o'er the sun,
An' off their face the happy look will run,
An', like a man that wrinkles up his brow
When trouble comes, them leaves are crinkled now.
An' so they change, from sorrow up to gay,
An' back again the whole day long; I say,
We got no use for any other flowers
Except them pansies in that yard of ours.

DON'T let the hogs suffer for water.

TOO many milch cows are filch cows.

AN unboiled dish rag becomes a rag weed.

READ the "Household tests" for oleo—page 430.

WE would like to know how you cool and handle your milk.

THE best thing a "wet blanket"—human or fiber—can do is to dry up.

HOW can you give your work a "square deal" without cutting the corners?

C. D. L. speaks a good word for the despised skunk in his fruit report on next page.

IT requires a strong antidote of shingle or slipper to correct the doting of some fond aunties.

WE want information about automatic stable cleaners or any devices for handling the manure quickly.

WHY not make the expensive farm machinery so strong and durable that the manufacturer need not expect to sell to the same man twice in a lifetime?

OUR fruit crop reports indicate that the wet weather has been a great hindrance to spraying, and insect troubles are likely to be a serious matter in consequence.

AT one time Holland led Europe as a dairy country. It began to encourage the oleo factory, while Denmark encouraged the cow. Of course, the Danes now lead the Dutch in dairying.

THE patron of a cheese factory will often refuse to buy cheese because it would cut down his monthly check! Yet he will use some of that money to buy meat or more expensive food.

IT seems that poultry men now sell large numbers of little chicks just as they are hatched from the incubators. This plan is said to suit many buyers better than purchasing the eggs.

THIS is the way one reader puts it: "THE R. N.-Y. is a treasure house of joy to the intellect and a source of profit to the pocketbook. May the kicker at Hope Farm be the only one in its clientage!"

No! There are patriotic kickers who serve their country with their toes.

SAN FRANCISCO has instituted quarantine against cases of consumption entering that port. This disease is extremely common in the Philippines, due partly to the climate, and partly to the susceptibility of the natives to the disease.

WE know of one farmer who cut potatoes for two acres, having all preparations made, expecting to plant the next day. Rain set in, and he was unable to plant for three weeks. Although the seed was rolled in plaster and spread out it decayed, and was a total loss.

Events of the Week.

DOMESTIC.—At Philadelphia, Pa., May 30, seven persons were drowned in the Schuylkill River, their boat being swept over the dam. . . . . Three persons were burned to death in a farmhouse fire at Watsema, Ill., May 30. . . . . At Wilmington, Del., May 31, three heavily loaded trolley cars ran away going down a steep grade, killing one man, fatally injuring another, and hurting many. . . . . In a gas explosion in a mine at Newcastle, Col., June 1, two men were killed and eight injured. . . . . In a great fire on the Isthmus of Tehuantepec, Mexico, over 70 persons were burned to death. . . . . Three persons were killed and 16 injured in a railway collision at Atlanta, Ga., June 3, where a switch engine dashed into a passenger train. . . . . Settlers in the Lander Valley, Wyo., are arming, and many families moving into the towns, as the Arapahoe Indians are going on the warpath. . . . . At Iron Mountain, Mich., June 4, eight miners were killed in the Chapin mine by the deadly fumes following an explosion of dynamite. . . . . June 2, a fire at Quincy, Ill., caused a total loss of $75,000. . . . . The town of Willits, Cal., was destroyed by fire June 5. . . . . Twenty tons of smokeless powder at the San Francisco Navy Yard was ignited by chemical action June 5, and in burning destroyed a valuable magazine. There was no explosion.

ADMINISTRATION.—The President and Cabinet decided, May 31, that the action of the Cuban Constitutional Convention was not a "substantial" compliance with the terms of the Platt amendment. The Secretary of War will convey this fact to the Convention. Courteously but positively the Cubans are informed in about 2,000 words that the President cannot accept the action they have taken, and the assumption is conveyed that they will rectify the mistake which they have made. It is pointed out that the President has no right to alter the purpose of Congress or to change the meaning of the directions given him by it, and that the action of the Convention cannot be approved without disobedience to the act of Congress. . . . . The President has determined that existing conditions do not require or warrant calling Congress together during the present Summer or making any change in the policy hitherto pursued and announced in regard to the Philippine Islands. The Cabinet was unanimous in the opinion that the authority to govern the Phillippines vested in the President by the Spooner amendment was ample. . . . . Andres L. Terry y Dortigos filed, June 5, the largest claim that has yet been presented to the Spanish Claims Commission. It is for $588,468.75, and is interesting in that part of the damage for which compensation is asked was not inflicted by Spanish troops, but by Cuban insurgents. Mr. Terry claims that the Spanish government was responsible for this damage, not only because it failed to protect his property from the insurgents, but because it gave them every opportunity to burn and loot.

PHILIPPINES.—The native lumbermen of Manila will petition the Philippine Commission for legislation making compulsory the use of Philippine lumber in insular improvements in preference to that imported from Borneo and the United States.

FARM AND GARDEN.—May 29, Gov. Stone, of Pennsylvania, signed the Snyder anti-oleo bill. Grangers and farmers' interests generally have fought earnestly for the passage of this bill.

At the recent meeting of the Florida State Horticultural Society it was stated that the white fly, hitherto regarded as the most formidable insect ever encountered in Florida, is giving way before the brown fungus (Aschersonia aleyrodis, Webber), insomuch that the most advanced growers of Manatee County now hardly bestow upon it a second thought. The San José scale, the brown rot and the curculio are spreading widely among deciduous fruits, and will require vigorous fighting by the growers to stamp them out.

Reports from Livingston County, N. Y., state that there is such a plague of biting flies in that locality that farmers are obliged to cover the horses' ears with nets, and take other precautions with their stock.

Several cases of anthrax on dairy farms are reported in Genesee and Niagara counties, N. Y. Farmers are having their stock vaccinated against it, and as soon as an animal dies of the disease it is cremated.

Following a secret conference of western Senators and Congressmen in Denver, the Congressmen of Nebraska and Wyoming have issued a call for a meeting to be held at Cheyenne, Wyo., June 20, at which Congressmen will be present from Nebraska, Kansas, North and South Dakota, Utah, Nevada, Colorado, Montana, Oregon, Washington and Idaho, to discuss the throwing open of the arid lands of the West to settlement, and plans for their irrigation. Senator Dietrich, of Nebraska, set forth a scheme for the employment of State and Federal convicts in building canals and reservoirs in the arid lands of the West, and suggested that the prison labor be guarded by United States troops, who would thus be given employment in time of peace. The workmen also would not come into competition with organized labor. Elwood Mead, for the Government's Irrigation Bureau, opposed the laying of the burden upon the Federal Government. Should the lands be thrown open, it is believed two-thirds of them will be secured by the large cattle interests.

The Secretary of State of Kansas granted a charter June 1 to the Farmers' Coöperative Grain and Live Stock Association, which was organized by the farmers at Salina a short time ago. The Association begins with a paid-up capital of $20,000, divided into 2,000 shares, and its object is to buy and sell, on commission or otherwise, farm products of all kinds, including live stock, and to establish and maintain yards, grain elevators and emporiums for the safe keeping, sale and distribution of farm products. The principal office shall be in Topeka, with subordinate offices, if necessary, elsewhere in the United States. The life of the corporation shall be 99 years.

Fruit growers visiting the Pan-American Exposition will find their headquarters at No. 8 Bidwell Parkway, Buffalo, which is within easy walking distance of the Exposition, and where they are likely to meet friends of similar interests.

The American Fruit Company of Porto Rico has been organized at San Juan, for the purpose of doing a nursery business in Citrus fruits, palms, bulbs and florists' stock for the New York market; also to grow Winter vegetables, pineapples and oranges. The officers are: President, Wm. R. Corwine, of the Merchants' Association of New York; secretary and treasurer, H. S. Rankine, assistant corporation counsel, city of New York; manager, F. M. Pennock, San Juan.

The New York fruit exhibit at the Pan-American Exposition is attracting much attention. There are 3,200 plates, chiefly of apples, of which latter there are 345 varieties on show.

The annual meeting of the Oregon State Grange was held at Albany, Ore., May 28-30. There was a large and representative attendance.

FRUIT PROSPECTS.

The prospects for apples are about one-half a crop, mostly Greenings and Fall fruit. Peach trees were loaded with blossoms. R. A.
Marengo, N. Y.

Greening, King, Ben Davis, Spy and Fall apples had a fair amount of blossoms. Baldwins are scarcely blossoming at all. Peaches have not blossomed as full as commonly. Cherries and plums have blossomed full; also prunes. G. A. M.
Sodus Center, N. Y.

The apple trees blossomed about 75 per cent; as for the varieties I could not say, but I think the Spy bloomed the least of any. Pears in most cases blossomed largely, and plums and peaches full. Not many peaches in this section. As for spraying there are not many who spray their fruit trees here. W. W. R.
Preble, N. Y.

Weather cool and rainy; most apples fell off. Stone fruits all sticking well; cherries and strawberries ripe and not abundant. Cutworms and grub worms doing great damage everywhere. Last week I saw where a skunk had dug out 45 grub worms in the space of a few rods of drill row. Protect the skunk and eject the skunk trapper from your premises. C. D. L.
Higginsport, O.

Prospects are good in this section for fruit of all kinds but apples. Grass is looking better than for several years. Early peas are coming out in blossom, and will be a good crop. I have not heard of Green pea-louse so far, but we many get it later on same as last year. We have had no frost this Spring to do any hurt. Tomatoes are being set out in the fields, and I noticed some a week ago in bloom. There are a good many cows kept in this section, and farmers are selling the milk to the Italian cheese factory for 90 cents per hundredweight.
Brant, N. Y. I. B.

The season here is very backward, as it has rained for nearly two weeks more or less and most of the time more. Some oats are not sown (June 1); very little corn is in the ground, and too wet to plow for corn and potatoes. Very light crop of apples in prospect, as the Baldwin did not bloom any and Greening very sparingly. Cherries light crop. Fly is doing serious damage in a great deal of wheat, although some red varieties are looking well, the best being the American Bronze. Canker worms have made their appearance, and all we can do is to let them eat, it being too wet to spray.
Penfield, N. Y. G. W. E.

The early varieties of apples have blossomed freely, and have set for an abundance of fruit. Winter varieties blossom very scantily, especially trees that bore last year (and the majority did). I know an orchard of 150 trees, all Greenings, 1,000 bushels last year, and not enough blossoms to fill two trees this season. My own orchard has not enough blossoms on Spy, Baldwin or Greening to fill one tree each. Roxbury Russet a trifle better. Sour cherries blossomed very full; plums and pears moderately; strawberries very full also. These conditions are general in the four or five towns through which I have passed more or less. H. D. M'K.
Euclid, N. Y.

In this section of Maine there have been many more rainy days and much more rain during this Spring than have been previously known. At intervals there have been a few days of sunshine, but when farmers had just begun to prepare the land for sowing another long storm has set it. Consequently only a small portion of the Spring work has been done. All fruit trees have blossomed fully, and there are no indications but that there will be a good crop of cherries, pears and apples. Not many plums and less peaches grow in Maine. Apple trees, though they bore last year, never looked more beautiful. They are now, June 4, just in full bloom.
Portland, Me. J. H. R.

Farmers are not very jubilant here; wet, 'way behind. Good grass crop promised on land that was well fertilized, but grass is no longer king. Poorest ice cream season to date we ever had; no hot sunny days. Seven acres potatoes in if they don't rot; shall harrow well just as soon as possible. All fruit but apples promise well. Small seeds not coming well. Some farmers have not been able to plant anything up to June 5, and are quite discouraged. Our dairy is doing finely and good demand for butter, which we turn out when cream is dead. We are making considerable cottage cheese, which brings a fair price, 10 cents per pound. This morning's milk was skimmed, buttermilk added to ripen, and at 3 P. M. was made and ready for sale. This beats our record. H. G. M.
Connecticut.

We are having a good deal too much of a good thing just now. It rains regularly every night and quite often all the time between two nights. Result is no corn or potatoes planted, much wheat turning yellow. Timothy meadows in many places much injured. Plums and peaches are rotting before they get jackets off. Curl-leaf in peaches is very bad on all heavy land. Duchess pears almost an entire failure. All late blooming apples like Hubbardston and Northern Spy have aborted, and a mighty slim show for any kind of an apple crop. As an offset, where land is not too wet, oats and barley are making splendid growth. Where it took last seeding, clover was never better; it is now more than knee high, as thick as a mat and with no show of blossoming yet. Thermometer runs along about 50 degrees mornings, and gets up to 65 to 70 through the day. Very little sunshine and with only one warm day so far this season, yet I never saw trees freer from fungus with the exception of Peach curl-leaf. J. S. W.
Niagara Co,, N. Y.

The Hudson River Valley Cherry Crop.

It is rather difficult at the present time to form an intelligent opinion on the cherry prospect. There has been a good setting of fruit with me and not very much dropping so far. The white varieties are showing some little rot in the past few days, and should rains continue will undoubtedly be a failure from this cause. We are very much in need of sunshine and dry weather.
Newburgh. J. R. C.

Sweet cherries set a very heavy crop, probably more than could be ripened, unless with exceptionally favorable conditions. The sour cherry trees were not so heavily loaded. The continued wet weather has caused many of the sweet cherries to fall from the trees. Should all that look healthy now on the trees hang on there will be a fair crop. On some trees rot has made its appearance. Unless we have continued dry weather soon this may spread and destroy the crop. So far there is a fair crop of both sweet and sour cherries on the trees.
Orange County. W. D. B.

The outlook for cherries in the Hudson River Valley and vicinity is most excellent. The blossoming of the trees occurred a little in advance of the excessive rainfall, and the fruit is set exceedingly well. There is at present a very good prospect for a very large crop. The Cherry aphis has made its appearance, and unless the trees are thoroughly sprayed with whale-oil soap or kerosene emulsion the drop will be seriously damaged. I have just made an inspection of my farm at Ghent, and find 500 apricot trees set with the finest crop I have ever known. The peaches are exceedingly heavy set, and if not considerably thinned will have very little value in them. On a four-inch branch of Japan plums I counted 37 well-set fruit, and we are thinning down to just four specimens. The prolonged wet period has already developed mildew on the apricots and they are rotting badly. If this is continued many days longer the peach and cherry crops will be damaged, even at this early period, from the same cause. We are spraying vigorously, even during this rainy period, with Bordeaux Mixture. GEO. T. POWELL.
Westchester County.

CROP AND WEATHER REPORT.

There is serious drought in the Central West, particularly in the Missouri and Upper Mississippi Valleys, while the Eastern States have suffered from the cold and continued rains. The temperature in all the district east of the Mississippi has been abnormally cool and very unfavorable for corn. Cutworms are doing considerable damage. During the latter part of the week the rains in the East stopped and a warm wave followed, causing a rapid growth in plants of all kinds. Winter wheat in the lower Missouri Valley is in bad condition owing to drought and fly damage. Harvesting has begun in Arkansas and will be in full blast in Kansas shortly after the middle of the month. Cotton has made but slow growth, and in the eastern part of the belt it needs cultivation, which has been prevented by the wet weather. The oat outlook in the Ohio Valley and Tennessee has improved. Apples are dropping largely, and the prospect in many important apple States is not promising. On the Pacific coast all crops are doing well. The California yield of wheat and sugar beets will be unusually large. Oregon hops are making good growth. Hungary, Austria, is a great grain district. Reports from there state that rust is rapidly spreading in wheat; that rye and barley are poor and that the sugar beet has suffered from vermin.

PAPER BOXES FOR STRAWBERRIES.

In THE R. N.-Y. a few weeks ago there arose a question concerning paper boxes, instead of the wooden ones. For six years we have used the paper boxes for strawberries with satisfactory results. The boxes we use are made by the Diamond Package Co. of Rochester, N. Y.; they make a box that is very neat and clean, being white paper, costing $2 per 1,000 in 5,000 lots, sold flat. They are also waterproof. They fasten together by locking the ends. We always put them up when our time is not worth much, and as we get fancy prices for our berries we can afford to give the box away and have clean ones every time we go to market. Wooden boxes get dirty and stained, but not worn out, and the fruit does not look well in soiled packages. By using a clean paper box, white and new, the appearance of the package will sell first every time, as I have often noticed. There is where the white paper box man gets to the front with his reputation in fine fancy fruit. Some one said that they get crushed, melt down and go to pieces. Our crates are made so that when a layer of boxes is put in the crate the tray does not rest on the top edges of the boxes as in the old way. There is a cleat on each end of the crate allowing one inch space from top of boxes for filling them full, so when we get to market we have an honest quart. When the cover of the crate shuts down it does not lie on the top layer of boxes, but there is an inch space between each layer, so you see the fruit goes to market in the finest of shape. As the boxes fit snugly together, the moisture from the berries does not wilt the boxes even if picked after a rain. From experience there is nothing like the white paper box for our use for strawberries. C. V.
Lyons, N. Y.

THE HAY CROP.—Many dealers in haying machinery say that sales thus far have been heavier than usual, and their reports indicate that the crop in the East will be exceptionally large. The wet weather has given the meadows such a start that if there is a reasonable amount of sunshine for the next two weeks, it would seem that hay producers may look forward to the biggest job of harvesting that they have had for a number of years. The indications are that in the Central West the crop will be rather light, owing to lack of rain. This will tend to even things up and prevent the usual low prices when the entire country has a heavy yield.

Woman and Home

From Day to Day.

DIFFERENT PATHS.

I lately talked with one who strove
To show that all my way was dim,
That his alone—the road to Heaven;
And thus it was I answered him:

"Strike not the staff I hold away,
You cannot give me yours, dear friend;
Up the steep hill our paths are set
In different wise, to one sure end.

"What though with eagle glance upfixed
On heights beyond our mortal ken,
You tread the broad sure stones of Faith
More firmly than do weaker men:

"To each according to his strength;
But as we leave the plains below,
Let us carve out a wider stair,
A broader pathway through the snow.

"And when upon the golden crest
We stand at last together, freed
From mists that circle round the base,
And clouds that but obscure our creed;

"We shall perceive that though our steps
Have wander'd wide apart, dear friend,
No pathway can be wholly wrong
That leads unto one perfect end."

—Credit Lost.

*

SOME young women are substituting a tiny velvet bow for the little pin or barrette used to gather up loose hairs at the back of the head. The hair is gathered together as for the pin, and the velvet, which is very narrow, slipped through and tied in a bow.

*

PURE grape juice gives a delicious flavor to ice cream; it is well worth trying. It is also excellent in jelly, and makes a fine flavoring for pudding sauce. A mold of grape-juice jelly served in a ring of whipped cream decorated with strawberries, is a handsome dessert formed of materials within the reach of a farm housekeeper.

*

STRAWBERRY pincushions are among the most popular of the small articles sold at the Women's Exchange in New York. They are made of the same shape as the strawberry emery, but the indentations are marked in with pins. Two small strawberry emeries hang from the top of the larger pincushion berry.

*

"WE shall all on us be dead some time, I reckon; it 'ud be better if folks 'ud make much on us beforehand, instid o' beginnin' when we're gone. It's but little good you'll do waterin' a last year's crop." So says sharp-tongued Mrs. Poyser, in Adam Bede. It is well to remember when tempted to give grudgingly of our best to those nearest us—to withhold kindliness, and lessen loving service—that we shall not pass this way again.

*

WOMEN are tacking a little posy of artificial flowers on their parasols this year, and very pretty are the flower-trimmed fluffy sunshades. But for practical use nothing is better than a 24-inch silk sun umbrella perfectly plain, which is useful for both sunshine and showers. Dark red is a desirable color, which gives a becoming shade; the handle should be a big crook or loop of natural wood. Such an umbrella goes well with everything, and always has a nice look.

*

MANY are the smart new belts offered for Summer wear. White alligator leather is one of the newest; it has a buckle of dull gold or silver. Burnt pigskin is another belt novelty. Gray suede with a frosted silver belt is very handsome. White piqué makes a very suitable belt for wear with shirt waists; it has a firm lining, and fastens with a nickel buckle. If one has a nice silver buckle or clasp, the piqué belt may be made at very small expense; line, and put two rows of machine stitching all around the edges. A stock collar of piqué may be suitably worn with it. Little girls are wearing belts of black patent leather with their frocks of white piqué, linen or pongee.

*

ONE of the most comfortable novelties offered by the large stores this season is the shirt-waist gown. With the shirt waist of ordinary design appears a simple skirt of the same material, the entire suit being furnished for a moderate cost. It is a very suitable style for country wear, and one to be recommended to the home dressmaker. Linen, piqué, cotton cheviot, madras and gingham are all desirable materials for shirt-waist suits. Such a suit of white corded lawn or piqué is very attractive.

3831 Misses' and Girls Wrapper, 8 to 16 years.

3765 Morning Gown, 32 to 42 in. bust

*

THE effect of climate upon one's moral being has puzzled a good many worthy people. Here is what an energetic New England woman says on the subject in "Penelope's Irish Experiences, a very amusing book by the author of "The Birds' Christmas Carol":

"There's nothin' like a Massachusetts Winter for puttin' the git-up-an'-git into you. Land! you've got to move round smart, or you'd freeze in your tracks. These warm, moist places always make folks lazy; and when they're hot enough, if you take notice, it makes heathen of 'em. It always seems so queer to me that real hot weather and the Christian religion don't seem to git along together. P'r'aps it's just as well that the idol-worshippers should git used to heat in this world, for they'll have it consid'able hot in the next one, I guess!"

The Rural Patterns.

The morning gown figured is made from challie in a soft dove gray, and is trimmed with bands of lace appliqué, but cashmere, wrapper flannel, Scotch flannel, and all similar materials as well as madras, percale and suitable washable fabrics are equally appropriate. The back fits smoothly, being arranged in shirrs at the waist line, below which the skirt portion falls in full folds. The fronts are slightly loose, but are arranged in gathers at the neck and held by a ribbon girdle at the waist. The sleeves are in bishop shape finished with cuffs. To cut this gown for a woman of medium size 11 yards of material 27 inches wide, 9½ yards 32 inches wide or seven yards 44 inches wide, will be required. The pattern No. 3765 is cut in sizes for a 32, 34, 36, 38, 40 and 42-inch bust measure; price 10 cents. The girls' wrapper or lounging robe is made of dimity showing pink spots on a white ground, but all washable materials are suitable as well as light-weight flannels and flannelette for the cooler days. The fronts are slightly full at the neck and widen out to form the skirt portion. The back is full at the neck and drawn in with gathers at the waist line. The neck is finished with a deep turn-over collar and the sleeves are in bishop style. At the waist is a ribbon that is tied slightly toward the left side. To cut this wrapper for a girl 12 years of age, six yards of material 27 inches wide, 4¾ yards 32 inches wide, or 4¼ yards 44 inches wide, will be required. The pattern No. 3834 is cut in sizes for misses of 8, 10, 12, 14 and 16 years of age; price 10 cents from this office.

The blouse waist No. 3812 is one of the very popular sailor styles. Piqué, duck, mercerized pongee, linen batiste, madras and cheviot are all available washable fabrics, while the various waist cloths and simple silks are equally appropriate. When made from any of the latter the lining should be used; but gowns that require to be laundered are better without the foundation and should have the V-shaped shield attached to the fronts beneath the collar. The waist is smooth across the shoulders at the back, but the fronts are each laid in two tiny pleats, and both fronts and back are drawn down in gathers at the waist line. The sailor collar is joined to the open neck. The shield and stock collar are attached permanently to the right side of the lining and hooked over into the left. The sleeves are in bishop style, finished with straight cuffs. To make this blouse for a woman of medium size 3⅞ yards of material 21 inches wide, 3¾ yards 27 inches wide, 2⅝ yards 32 inches wide, or two yards 44 inches wide will be required. The pattern No. 3812 is cut in sizes for a 32, 34, 36, 38 and 40-inch bust measure; price 10 cents. The misses' waist No. 3771 has the back laid in straight tucks at the center back, which are overlapped at the waist line to produce the desired V. The fronts include the center box pleat, through which the closing is effected, with a group of three full-length tucks at each side and successive groups of graduated length that extend to the shoulders, and provide fullness below. The sleeves are in bishop style with pointed cuffs that lap over from the opening at the seams. The neck is finished with a neckband and can be completed by the collar provided in the pattern, by one of white linen, or by ribbon arranged as a stock as preferred. To cut this waist for a miss of 14 years of age 3¼ yards of material 21 inches wide, 2½ yards 27 inches wide, 2½ yards 32 inches wide or 1⅞ yard 44 inches wide will be required. The pattern No. 3771 is cut in sizes for misses of 12, 14 and 16 years of age; price 10 cents from this office.

3771 Misses Shirt Waist, 12 to 16 years.

3812 Woman's Blouse, 32 to 40 in. bust.

Pioneer Experiences.

One of the accomplishments possessed by the pioneer farmer's wife, was the art of painting floors. This became necessary because the rich black soil was so fine that it would track into the house, and no amount of mopping would make the floors look inviting. The oil to be used was first boiled until it would crisp a feather, some litharge was stirred in for its drying qualities; it was then thickened with French yellow, and white lead was also added, or red lead to make a shade that best suited the taste of the artist, the lead making the paint harder and more durable. Then, the room being emptied, the operator, in appropriate costume, proceeded to paint the floor. At first flat sticks were laid down here and there, and boards were laid on them so that there was a place for the cook to walk without injury to the work; but it was found by practice that it was better to lay smooth boards flat, along where it was necessary to walk, as it seemed to mar the paint less. After the first coat a day was allowed for it to dry and then the finishing touch was added by applying the last coat. It was troublesome to live while the floor could be sufficiently dried, but patience brought it out all right. If the housekeeper could keep the family off the paint for a week, the beauty and lasting qualities of the paint would pay her well for the trouble. Afterwards the boards were mopped every day with skim-milk or milk and water which had the effect of making them smooth. The month of May was the usual time for this, it was one of the accompaniments of the annual housecleaning. I have heard some old ladies with pardonable conceit declare that they could mix paint that would outshine in beauty or wearing qualities any that was prepared in the shops. The work of painting was hard while it lasted but was a real labor-saving in the end, besides adding much attraction to the home. Papering was much resorted to, both for the looks, and for the added warmth it gave to the cheaply constructed farmhouse. If nothing else was procurable, newspapers were freely used in the Summer kitchen at least. A paste of rye flour was found to be excellent for use, it causing the paper to adhere to the rough walls better than other preparations.

AUNT RACHEL.

TEACH us to love and give like Thee!
Not narrowly men's claims to measure,
But daily question all our powers,
To whose cup can we add a pleasure?
Whose path can we make bright with flowers?

—Whittier.

Why lack for goodly company
When cheerful thoughts are cheap?
And why, since it must rest with you,
Friendship with others keep?
Your sable musings and your drab
But sorry comrades are.
And choosing, as needs be, why not
Such grim acquaintance bar?

—St. Louis Republic.

Free for a Club of Four.

Here are 44 first-class tools for repairing shoes, rubber, harness and tinware. We are going to give no arguments why you should have them. The reasons and uses are apparent to every one. There is nothing like mending a hole, putting in a stitch, or driving a nail in time. It always saves time and money. It often saves lives. The price is $2 alone, but it need cost you only $1. Send us one new subscription with $1, and $1 extra—($2 in all) and we will send you the outfit complete, or we will send it to you free for a club of four yearly subscriptions at $1 each.

An Act of Insubordination

PART II.

"I pieced this quilt years ago," said Mrs. Sherwood, when they were at last ready to settle down to the tying. "There are a good many pieces that were given me by folks we both used to know. As we work let's see how many of the pieces we can remember."

All the forenoon they worked steadily and talked fast. The pieces in the quilt recalled to mind all their old-time friends. Some were living, some dead and others lost sight of, but there was something to be said of each one. They were so anxious to finish the quilt that they ate only a hasty lunch at noon. They were rather silent over it till suddenly Mrs. Doane laughed gleefully.

Mrs. Sherwood looked up expectantly. "What is it, Mary?" she asked.

"I've been worrying about 4 o'clock," she said. "I've tried not to show it, but it has been on my mind. I don't want to be come after and carried home, and I've just thought what I'll do. I'll start home across lots at four, and when Emily gets here she won't find me. As long as I've been naughty already I'm going to make a day of it. I probably never shall act so again. Do you know, I feel like an old horse that's been shut up in the barn all Winter and when he has a chance to get out he can't keep from capering."

"I feel the same way," confessed Mrs. Sherwood.

"Now that walk this morning; you don't know what it was to me. I always used to think it was the most beautiful path in the world and I think so now, though it has changed—trees cut off in some places and grown up in others." She did not mention losing her way; she was a little ashamed of it.

Mrs. Sherwood looked at the clock. "I hate to think of your going home, but I guess we can finish the quilt."

"I shall be up again before I go," said Mrs. Doane. "That is, unless Emily is so displeased she won't bring me. I don't blame her for being put out. It is a queer way to act on the third day of my visit. I expect she'll feel real ashamed of her mother cutting up so."

"I don't believe it," said Mrs. Sherwood. "She'll tell folks how smart you are for seventy-one."

The quilt was finished at half-past three and all evidences of their guilt effaced. Mrs. Doane began to be nervous and at quarter of four declared she must start. Emily might take a notion to come earlier. The two friends walked slowly down the lane together, as they had done in their girlhood. At the woods they parted. "I feel real mean to leave you to face Emily alone," said Mrs. Doane, "for I don't doubt she'll be a good deal r'iled. Well, good-bye, I've had a lovely time."

She walked on slowly till she was more than half way home, when a new thought struck her. "I'll get supper before Emily gets home," she said. "She won't be back before five, and if I hurry I can have supper all ready when she comes."

She walked along briskly, reaching home only a short time after her daughter had started. The door was locked, but she knew where to find the key. She let herself in and soon had a fire kindled and supper started. As she walked about setting the table she sang softly.

"Well, Mother, if you haven't given us a day of it!" Emily exclaimed when she came home. "Scaring me out of my wits till I found your note, and then sending me on a wild goose chase after you this afternoon. I declare, I'd like to shake you." All Emily's usual good humor was gone. It was Mrs. Doane who was placid now. "I'll help you unharness," she said mildly.

"No," said Emily shortly, "I'll leave the horse for Henry or the boys to 'tend to I've got to go to work now; it's late."

Mrs. Doane followed her into the house.

"And you've gone and got supper!" Emily exclaimed. "Well, Mother, if you don't beat all! What has got into you? I should have thought you'd been tired enough with all that walk—and goodness knows what you did while you were up there—without going to work and getting supper. You'll be sick to-morrow."

"I don't care if I'm sick a week," Mrs. Doane declared calmly. "I've had a beautiful day. I've done just what I've wanted to and the walk was just lovely. All the rest of my visit I'll be quiet and proper, but I've had one beautiful day and nobody can get that away from me."

Emily sighed resignedly. "Well, I'm glad you've had a good time. After all, I suppose folks have got to enjoy themselves in their own way. I declare, I should think when Mattie and Ellen hear of this they'd be thankful their mother is quiet and sensible and don't act so."

Mrs. Doane smiled. "I guess they will be thankful," she said demurely.

SUSAN BROWN ROBBINS.

Rural Recipes.

Rye Breakfast Rolls.—Two cupfuls milk, two cupfuls rye flour, three eggs, half teaspoonful of salt, tablespoonful of sugar. Beat the eggs, add milk and sugar. Stir this into the flour, to which the salt has been added. Have the tins warm when the dough is put in and bake 25 minutes in a quick oven.

Crumb Pie.—Soak a pint of bread crumbs in milk. Beat three eggs; add half a cup of sugar. Line two pie plates with crust and strew over enough raisins

3828 Misses' Sailor Shirt Waist, 10 to 16 years.

3805 Square Yoke Nightgown, 32 to 42 in. bust.

to cover bottom. Add the bread crumbs to egg and milk, sifting in a bit of cinnamon, pour over the raisins and bake about 30 minutes.

Walnut Cake.—Cream two-thirds of a cupful of butter with one cupful of sugar. Separate three eggs; beat the yolks until creamy and add to butter and sugar; then add one cupful of milk alternating with three cupfuls of flour (reserve enough of the flour for the nuts), add two teaspoonfuls of baking powder, one cupful of nut kernels chopped, and last of all fold in the whites of the eggs beaten to a stiff froth. Bake in a loaf tin in a moderate oven from 45 minutes to one hour.

Finnan Haddie with Eggs.—Soak one medium-sized fish in boiling water for five minutes, then broil on both sides over a clear fire. Pull off the flesh in small strips, lay them upon a hot platter, sprinkle with half a saltspoonful of white pepper and half a tablespoonful of melted butter. It will need no salt. Have ready five eggs delicately scrambled and seasoned with a half-teaspoonful of salt and one-fourth as much pepper. Turn the scrambled eggs over the fish and serve very hot.

Marlboro Pie.—Into two cupfuls of stewed and sifted apple sauce stir while still hot two tablespoonfuls of butter; beat the yolks of two eggs, add one cupful of sugar, the juice of one lemon and half the rind grated, one-quarter teaspoonful of salt and one-half cupful of fine cracker crumbs; mix thoroughly and turn into a plate lined and bordered with rich paste; bake in a moderate oven, and when done make a meringue with the whites of four eggs, four tablespoonfuls of powdered sugar and one tablespoonful of lemon juice; pile it lightly over the surface and set it in a moderate oven until slightly colored; serve cold.

Raisin-Cake Squares.—Sift and dry half a pound of flour, rub into this two ounces of butter and a very little lard, add three ounces of sugar, a teaspoonful of baking powder and six ounces of stoned raisins. Beat two eggs with a spoonful of milk, and add to the dry ingredients; add a pinch of ground cinnamon and beat all to a light batter; pour into a greased pudding tin and bake in a sharp oven; when cooled a little cut with a hot knife into squares and serve while still warm.

Fried Rolls.—Soak one-half cake of yeast in one-fourth cupful of warm water. Scald one cupful of milk and add to it one heaped tablespoonful of butter, one rounded teaspoonful of salt. When the milk is cool add the yeast and stir in flour enough to make a smooth batter. Beat the white of one egg stiff, turn it into the batter and when well mixed stir in enough more flour to make a stiff dough. Knead it until smooth. Let it rise in a warm place till light, then knead it down, take out pieces as large as an egg, make them first into balls, then into finger rolls. Let them rise some distance apart and when light drop them into hot fat and cook brown.

A Fresh-Air Pantry.

A shaded, airy hall or porch is a good situation for a fresh-air closet in which to store cooked food from one meal to the next. It is only a frame box with door and sides of wire gauze and shelves across the inside. It is best made fast to the wall at such a height as to be safe from prowling cats, and should have further a trusty lock. Put away food in it in clean earthen dishes, never in any sort of metal, not even in silver. Slip each dish into a separate cheesecloth bag, and twist the bag end tight. If ants, black or red, discover the closet, paint the wood box all outside with camphor once a fortnight. Twice a year take down the whole contrivance and scald it outside and in with boiling soda water. All manner of food keeps beautifully in it from one meal to the next. Things may be put in it while still warm. If they have to go into a tight, unventilated place, as a refrigerator, they must needs be stone cold or they will get soggy and smelly.

Always set away cooked things in uncovered dishes. Wire gauze dish covers will keep out dust and admit of ventilation. They are, however, too costly for many purses. A good substitute is a hoop or oval of stout wire with either cheesecloth or mosquito net sewed firmly over it. Make the hoops of sizes to fit all sorts of dishes, or, rather, of sizes to stand an inch beyond the edges they must cover. The weight of the wire holds them well down. Every week drop the covers in a wash boiler with water and a little soda, boil for five minutes, and dry in the sun. Light and lime, the best of all antiseptics, should be relied on to keep the fresh-air closets sweet. Hang a bag of quicklime somewhere, and change the contents as fast as the lime slakes. In country or suburban houses ants are often a plague. A ring of air-slaked lime an inch wide and a half inch deep will keep them out of a dish holding food. They cannot crawl over a shelf thickly dusted with powdered lime. But since they travel always by definite roads, it is well to find the path and block it by a smear of coal or pine tar applied, if possible, outside the pantry. Save in freezing weather, keep fruits, vegetables, etc., in the fresh-air closet until wanted. Cooked meats and salt ones can stay there the year round. It is the place for such things as cheese, nuts, raisins, dates and olives. All of these lose flavor or grow rank by keeping in a warm place, or by suffering great alternation of temperature.

MOTHERS.—Be sure to use "Mrs. Winslow's Soothing Syrup" for your children while Teething. It is the Best.—*Adv.*

He that gives quickly, gives twice.
Give if thou canst, an alms; if not, afford
Instead of that, a sweet and gentle word.
—Herrick.

We can't choose happiness either for ourselves or for another; we can't tell where that will lie. We can only choose whether we will indulge ourselves in the present moment or whether we will renounce that for the sake of obeying the divine voice within us—for the sake of being true to all the motives that sanctify our lives. I know this belief is hard; it has slipped away from me again and again, but I have felt that if I let it go forever I should have no light through the darkness of this life.—George Eliot.

THE "1900" FAMILY WASHER FREE.

Greatest Invention of the Age. Labor and Expense of Washing Clothes Cut in Two.

No More Stooping, Rubbing or Boiling of Clothes.

Every Household Needs One.

THE "1900" BALL-BEARING FAMILY WASHER

will be sent absolutely free to anyone answering this advertisement, without deposit or advance payment of any kind, freight paid, on 30 days trial. The 1900 Ball-Bearing Washer is unquestionably the greatest labor-saving machine ever invented for family use. **Entirely new principle.** It is simplicity itself. There are no wheels, paddles, rockers, cranks or complicated machinery. It revolves on **bicycle ball-bearings**, making it by far the easiest running washer on the market. No strength required, a child can operate it.

No more stooping, rubbing, boiling of clothes. Hot water and soap all that is needed. It will wash **large quantities of clothes** (no matter how soiled) **perfectly clean in 6 minutes.** Impossible to injure the most delicate fabrics. As the Sup't. of the Savannah Yacht Club says:

"It is a wonder. Our washing is very large and "we have always had two women on Monday and one "on Tuesday. Our cook and the yard boy **now do** *"the washing in 4 hours much better than before."*

NEWMAN, Ills., July 5, 1900.
I can testify that the 1900 is the best washer and the easiest running machine. It will **absolutely clean** the clothes, cuffs, and bottoms of ladies white skirts better than can be done by hand. The washings that took my wife from 5 to 7 hours to put out by hand, can easily be done in 2 hours. R. A. SKINNER.

KENSEE, Ky., March 21, 1900.
I did a double washing for myself yesterday and made 65 cts. from my boarders, besides all my cooking, milking and housework. It takes less soap with your machine than in the old way. I have no need of the washboard any more Mrs. L. A. BARTON.

ONALASKA, Wis., Jan. 4, 1901.
We are a family of 5 and as I had a 3 weeks wash it was an immense one. Had it all out in 3 hours and never had nicer looking clothes. I did not even put my hands into the water. I cannot too strongly recommend the "1900" washer. Mrs. J. M. WILSON

BUSINESS BITS.

ONE housekeeper of our acquaintance says that she has tried many washing machines, but the only one which has met her expectations is the 1900 washer. It is a great labor saver, removing all the dirt, and there is absolutely no risk of tearing the clothes. No housewife should be without one—just see the liberal offer made by the 1900 Washer Co., of Binghamton, N. Y., in this issue.

THE name "Dederick" has been so long associated with the making of good hay presses, Mr. Dederick having been the originator of the hay-baling idea, that a new press from his factory is certain to attract more than passing attention. We believe that hay growers everywhere will welcome Dederick's new continuous belt hay press. We know everyone who grows hay will be interested in it, both on account of its good work and its low cost. Send for circulars to P. K. Dederick's Sons, Tivoli St., Albany, N. Y.

WE are in receipt of an interesting letter from Minard D. Harder, Cobleskill, N. Y., in reference to the new management of the Empire Agricultural Works, with which he has been connected since its establishment, in 1859, and which he owned and managed from 1870 to 1897 when, on account of impaired health, he resigned the business to his son, George D. Harder, who conducted it until his death in February last. After being taken ill, he gave his brother-in-law, Edgar S. Ryder, power of attorney, also making him sole executor of his estate—his son, Frank H. Ryder, Mr. Harder's grandson, acting as general office manager, a young man of unblemished character, who, through his four-year college course, was training himself for a business career, and that business the Harder Agricultural Works. Mr. Edgar S. Ryder is a man not only of irreproachable character, but entirely responsible financially. In regard to the quality of the machinery sent out, it contains the same perfect material and superior workmanship as heretofore, its construction being under the vigilant eye of the same superintendent, S. S. Myers, who has held this position, as also many of the skilled workmen under him for many years. The celebrated Fearless horse power thrashers and cleaners have been manufactured and sold by this house now for 38 years. The Harder round silo with continuous opening front was originated and patented by George D. Harder. This house enjoys an enviable and merited reputation, and the present management can be depended upon to maintain it in the future.

THE expression "O. K." is attributed to President Jackson, who is said to have written "O. K." for "all correct." The letters are now used very generally throughout the United States to signify that all is correct. Elsewhere in this issue is shown an illustration in connection with which the letters "O. K." are used. The picture shows a farmer providing himself with the McCormick binder. With the machine he is buying he will have no difficulty in harvesting his grain crops successfully, and any farmer could well afford to imitate this man. If you haven't a McCormick call on the McCormick agent in your locality, or write at once to the McCormick Harvesting Machine Co., Chicago, U. S. A.

RALPH L. SHAINWALD, president of the Standard Paint Company, New York, the manufacturers of the well-known P&B products, sails for Europe on the Fuerst Bismarck, June 6, on a business trip, remaining abroad until October. The P&B goods are very popular abroad. In China, Ruberoid roofing covers the barracks of both the United States and German troops quartered there. Ruberoid is also used in the De Beers mines in South Africa, and a large lot went to the Klondike fields in Alaska a few months ago. Ruberoid is adaptable to all climates; hence its universal popularity.

Disease and death often lurk in a continuously neglected cold, when it might be speedily eradicated with a few doses of Dr. D. Jayne's Expectorant—*Adv.*

Two Grandsons of Exile, sire of 86 tested cows. Solid Color, two and four months old. Handsome. J. A. HERR, R. D. No. 4, Lancaster, Pa.

SHIP your Berries, Cherries, Butter, Southern Truck and all Fruit to the best market. Samuel Whitton, Com. M'ch't, Utica, N. Y. Our market is good on Fruit at all times. Ref. furnished.

That Drouth

which usually strikes the *Eastern States* early in June, and always damages crops, can be mitigated by the judicious use of 150 lbs of

Nitrate of Soda

per acre about the middle of May. It invigorates the growth and enables the plants to pass through this trying period unscathed. Try it on your potatoes and garden crops. A request for free literature and ***list of dealers*** will receive prompt attention if made to **John A. Myers**, 12-O John St., New York City.

The New Horticulture

BY H. M. STRINGFELLOW.

We do not hesitate to say that this is one of the most interesting books on horticulture that ever was printed. Most reading farmers have heard of the now famous "Stringfellow Method" of planting trees, but few understand clearly what it is. This book tells the whole story in clear-cut, forcible style, which all can understand. Not only is the theory of close root-pruning carefully explained, but the general principles of gardening and fruit-growing are discussed. Mr. Stringfellow is a practical gardener, and he gives his own experience. We commend the book to all without reserve. New Edition, paper covers, 50 cents.

THE RURAL NEW-YORKER, New York.

BOOK BULLETIN

For Sale by The Rural New-Yorker

THOMAS'S American Fruit Culturist, 758 pages. Illustrations and descriptions of all fruits and nuts grown in this country. Methods of culture, etc. Price, postpaid, $2.50.

SOILING, Ensilage and Stable Construction, by F. S. Peer. Full details of the best methods of growing and feeding soiling crops. Valuable hints on barn building. Price, postpaid, $1.

FITTING Sheep for Show Ring and Market, by W. J. Clarke, 248 pages, 36 illustrations. Tells how to care for the flock to get the best results for exhibition and market purposes. Price, postpaid, $1.

THE RURAL NEW-YORKER,
409 Pearl St., New York.

Market Briefs

PICKED UP HERE AND THERE

SMALL FRUIT NOTES.—Large quantities of strawberries are arriving, and some improvement in quality is noted. Prices, however, remain low. There are a good many North Carolina huckleberries of fair quality wholesaling at 10 to 15 cents. The sale for them is limited, however, and from now until the Oswego crop arrives, strawberries will hold first place in the small-fruit market, making blackcaps, blackberries and all others take a back seat. Of late trade in raspberries, both black and red, has not amounted to much, but blackberries of good quality usually do very well.

TO TEST GAME LAWS.—The search for game mentioned last week was continued until about 15,000 pieces of forbidden game were found in this one cold-storage house. Suit is to be brought against the owners of the birds, most of whom belong to the Game Keepers' Association. They purpose to test the constitutionality of the law and have put up $10,000 for this purpose. It is said that an agreement has been made that if the game people lose, their fines shall not exceed $10,000. It is well to have this matter decided definitely one way or another. If this law is not constitutional, it certainly ought to be repealed; if it is, violations of it should be met with the most severe penalties, and no favoritism shown.

WATERMELONS.—Several shipments have arrived from Florida. Those of reasonably good quality sell at very high figures, wholesaling at 40 to 65 cents. All that we have seen have been of the long variety. Reports from Georgia indicate that the acreage this year, both of watermelons and cantaloupes, is not far from 20 per cent less than last, and at present the vines do not look promising. It is rather early to make any definite predictions as to prices for the bulk of the crop, but there is reason to believe that they will be higher, except perhaps at the period when the great rush from both Southern and Central districts comes. Some of the disastrous gluts in the melon market in this city that have occurred in past years might have been prevented if shippers had known the conditions better, and diverted part of their crop to other points.

PEACHES are coming from Georgia and California; but they are green, uninviting and difficult to sell. Few care to buy such inferior peaches so long as there are plenty of fine oranges, cherries and apples to be had. It is a great mistake to ship peaches green. Unlike pears they do not ripen well off the trees. Last year we saw large Elbertas here that were not fit to eat. If left on the tree a little longer they would have been excellent. Of course, it will not do to leave them until "dead" ripe, if they are to be shipped a long distance, but certainly those that are hard as stones when they reach New York must have been picked too soon. A man who buys a basket of nice-looking but hard and tasteless peaches is not likely to invest again, while, if he gets what pleases him he may buy freely. Multiply this man by 10,000, and it is easy to see that this is not an unimportant matter. It may be difficult to figure things out so that the fruit may reach the consumer in just the right shape, but it is necessary to come as near to it as possible if the best results are to be had.

GREAT TRADE IN COCOA.—The value of this product brought into the United States during the past year was more than $5,500,000. This represented about 21 tons of cocoa leaves, shells and beans, twice as much as was used 10 years ago. There has been a steady demand for chocolate in candy making for a long time, but it is only recently that people in this country have used this product to any extent as a beverage. Now nearly all hotels and restaurants supply it in addition to tea and coffee, and it is also found daily on the tables of many families. When properly prepared it is wholesome and free from the objectionable features of strong tea and coffee. In most restaurants it is the custom to put a little dry cocoa into a cup, pour on hot water and milk, stir and serve at once. This does not cook the cocoa sufficiently to get best results, and it has a decidedly raw taste. During the process of boiling, a little vanilla should be added; this gives the rich flavor of French chocolate. Cocoa is adulterated with flour to some extent, and in the cheaper grades considerable of this is worked in. This product comes from the tropical portions of South America and Africa, and from the East and West Indies.

BARN PASTURE FOR COWS.

A Study for Soiling Crops.

CRIMSON CLOVER.—I said last week that there was green forage enough in sight on the farm to last until July 15, with a surplus to be cut for hay. As we looked over the level stretch of land great streaks or gashes of red appeared where the Crimson clover had headed out. This clover was seeded last Fall in the corn, and in spite of the dry season it made a good growth. It was all ready to cut and haul to the barn for feeding, or it may be turned under and used to feed another crop of corn. Prof. Voorhees has weighed, sampled and analyzed this crop with great care. He has demonstrated that such a crop as is growing at the Station is fully equal to 15 heavy loads of manure per acre. Cattle are very fond of the green clover. The hay is also very strong, but it is hard to cure in a season like this, when there is too much rain. In dairy farming, where a good ration of silage is fed the hay or dry fodder should be strong in protein. Alfalfa, Crimson clover, cow peas or oats and peas are best for the dry part of the ration. In this soiling system Red clover has been about dropped out.
